INDEX TO VOLUME 122

Mining and Scientific Press

January to June 1921

	Page		Page	
A				
Abraham Lincoln	219	Baker, F. D., obituary	859	
Adicks, L. Copper Refining, book review	609	Balliet, Letson	Oxy-acetylene welding and cutting	523
Aetna company, Hercules Powder Co. absorbs	863	Ball-mill lining, steel rails as	E. B. Morse	465
Afinity of oil for mineral	H. W. Reed	Bancroft, W. D. Applied Colloid Chemistry, book review	309	
I. M. & M. E.	645	Barnes-King Development Co.	434	
Alaska, mining in 1920	163	Company report	572	
Alaska Gold Mines Co.	R. B. Brinsmade	Benefaction, a noble	Editorial	114
Alaska Juneau Gold Mining Co., company report	656	Benguet Consolidated Mining Co., company report	572	
Ditto	Editorial	Benitez, F. Rising tide of color	351	
Mill	V. C. Clauson	Bigness, the craze for mere	Editorial	664
Allen, A. W. Book-reviewing	708	Bin, louvered	Newton L. Hall	593
Ditto	Chuquicamata enterprise	Ditto	W. M. Hutton	323
Ditto	Cutting metal with a steel disc	Storage, with louvered hoppers	Newton L. Hall	88
Ditto	Institute affairs	Bingham Mines Co., company report	572	
Ditto	Recovery of Nitrate from Chilean Caliche, book review	Black Range tin district of New Mexico	F. S. Naething	557
Ditto	Regeneration of cyanide during precipitation	Black sand, gold in	J. Gross	869
Ditto	Science and Life	Ditto	J. S. Taylor	833
All-round engineer	Editorial	Sand, recovery of gold from	J. A. Davis and J. Gross	504
Almaden quicksilver mine in Spain	H. W. Gould	Blasting with liquid air	843	
Aluminum	784	Blue Horse mine	573	
During 1920	431	Blue-sky laws	Editorial	665
Amalgamating practice	W. J. Williams	Book-reviewing	A. W. Allen	708
Amalgamation in stamp-mills	W. Motherwell	Ditto	F. H. Mason	833
In the presence of oil	L. C. W. Graefe	Borcherdt, W. O.	Institute affairs	217
American Engineering Council	573	Borzynski, F.	Arizona Silver Mines mill	717
American industry in the War	Editorial	Botsford, R. S.	Placer mining in Russia	671
American Mining Congress	436, 885	Bramble, C. A.	Prospecting in Canada	183
American Smelting & Refining Co.	377, 396, 505	Braschi, V. M.	Origin of Spanish names	805
Company report	608	Brazil, high-level diamond deposits of	A. M. Pontie	397
American Trona Corporation	C. G. Fowler	Brinsmade, R. B.	Alaska Gold Mines Co.	149
American Zinc, Lead & Smelting Co., company report	608	Britannia Mining & Smelting Co.	468	
Amigo	Economic interests	British Columbia, mining during 1920	61	
Anaconda Copper Mining Co.	411, 425	Broad-lode hypothesis	Editorial	37
Another apex decision	Editorial	Ditto	A. G. Ologist	79
Antimony	456	Ditto	L. S. Ropes	284
Apex decision, another	Editorial	Ditto	F. L. Sizer	150
Applied Colloid Chemistry, book review	W. D. Bancroft	Broken Hill Proprietary Co., Ltd., report	311	
Are drill-bits magnetic?	335	Strike	22	
Argentina, manganese mining in	389	Brooks, Lyman H., Jr.	Cooke City and the New World mining district	682
Arizona Silver Mines mill	F. Borzynski	Brunton, David W.: Consulting engineer, an interview	T. A. Rickard	745
Artificial Light, book review	M. Luckiesh	Ditto	History of the Huelva district	130
A. S. & R. and smelter contracts	721	Brunton sampler	752	
Reduces expenses	611	Bunker Hill & Sullivan Mining & Concentrating Co., company report	850	
Asbestos, South African	844	Smelter	T. A. Rickard	42, 47
Assay-furnace, new type of oil-fired	E. K. Craig	Bureau of Mines, professional advice from the	Editorial	801
Assessment work	865	Burgess, J. A.	Valuing partly exhausted mines	703
Ditto	W. K. Whitmore	Burnham, M. H.	486	
Work, suspension of	E. Hedburg	Business expansion abroad	Editorial	518
Austin, L. S.	Science and Life	Butson, H.	The strike at Tonopah	833
Automotive Ignition Systems, book review	609	Butte & Superior Mining Co., company report	850	
E. L. Consoliver and G. I. Mitchell	609	Butte mine operators, ultimatum to unions	431	
B				
Bain, H. Foster	Editorial			
Ditto	Mining as a business			
Bain's Mr., appointment	Editorial			

C

Cahill, W. E. Electric-furnace practice at Treadwell	355	Jim Butler Tonopah Mining Co.	607
California's metal output in 1920	87	Judge Mining & Smelting Co.	818
Callahan, J. A., obituary	859	Kendecott Copper Corporation	818
Callahan Zinc-Lead Co., company report	608	Lake Shore Mines, Ltd.	478
Calumet & Hecla	431, 433	La Rose Mines, Ltd.	572
Company report	607	McIntyre Porcupine Mines, Ltd.	311
Cam Design and Manufacture, book review		Miami Copper Co.	731
F. B. Jacobs	609	Mt. Bischoff Tin Mining Co.	607
Camp Bird, Ltd., company report	731	Mt. Lyell Mining & Railway Co., Ltd.	312
Cams, Elementary and Advanced, book review		Mt. Morgan Gold Mining Co., Ltd.	312
F. DeR. Furman	686	Mysore Gold Mining Co.	607
Canada, prospecting in	183	Natomas Mines of California	572
C. A. Bramble	436	Nipissing Mining Co.	656
Canadian Consolidated Mining & Smelting Co.	436	North Broken Hill, Ltd.	312
Canadian metal and mineral production	395	North Butte Mining Co.	731
Mining in 1920	197	North Star Mines Co.	607
Carman, E. S. Foundry Molding Machines and Pattern Equipment, book review	686	Old Dominion Co.	607
Carnegie, Andrew, Autobiography of, book review	34	Oriental Consolidated Mining Co.	478
Cause and control of lead poisoning		P Phelps Dodge Corporation	818
W. L. Slemmons	427	Portland Gold Mining Co.	572
Central Eureka Mining Co., company report	818	Ray Consolidated Copper Co.	850
Champion Reef Gold Mining Co. of India, company report	607	Santa Gertrudis Co., Ltd.	731
Chemical Analysis of Special Steels, book review		Shattuck Arizona Copper Co.	607
C. M. Johnson	109	Silver King Consolidated Mining Co. of Utah	607
Chief Consolidated Mining Co., company report	311	St. Joseph Lead Co.	478
Shaft	741	Superior & Boston Copper Co.	478, 608
Chile Exploration Co.	779	Tennessee Copper Co.	850
Chilean nitrate and synthetic compounds		Tomboy Gold Mines Co., Ltd.	311
F. H. Mason	452	Tonopah Belmont Development Co.	731
China, mint for	292	Tonopah Extension Mining Co.	818
Silver prices and famine in	284	U. S. Smelting, Refining & Mining Co.	731
T. T. Read	430	United Eastern Mining Co.	818
Chlorination of natural gas		Utah Consolidated Mining Co.	608
Chiquicamata enterprise	779, 835	Utah Copper Co.	608, 850
A. W. Allen	629	Victoria Copper Mining Co.	572
Clauson, V. C. Alaska Juneau mill	629	Yukon Gold Co.	312, 731
Clinton, G. Conductivity of Solutions, book review	610	Compressed Air, book review	Theodore Simons
Coal mines, electricity in	228	Compressed Air Plant, book review	R. Peele
Storage of	131	Conditions in Mexico	Editorial
Coal Washing, book review	309	Conductivity of Solutions, book review	G. Clinton
Coalite	849	Congo, Belgian, gold mining at Kilo	
Cobalt	644	Cooking v. Silver King Coalition	Editorial
Coghill, W. H. Educating v. drop-forging	160	Consolidated Arizona Smelting Co.	432
Collins, G. E. Institute expenditure	218	Consolver, E. L. and G. I. Mitchell	Automotive Ignition Systems, book review
Ditto	871	Consumption of reagents used in flotation	
Colombia, treaty with	555	T. Varley	262
Colombian treaty	640	Convention, reporting a	Editorial
Colorado, low-grade and complex ores in	263	Cock, Alfred A. Defence of Minerals Separation	
Colorado School of Mines	541	Cocke, D. W., obituary	795
Ditto	247, 552	Cooke City and the New World mining district	
Ditto	413	Lyman H. Brooks, Jr.	682
Ditto	773	Copper	Editorial
Coloring of glass	806	Future of	Edwin C. Holden
Ditto	872	In 1920	98
Commodities, prices of	477, 655, 798	Metal from the consumer's point of view	287
Comodoro Rivadavia oilfield	726	Mining in Newfoundland	T. E. Wells
Company meeting	639	Production, curtailment of	
Company reports:		Refining, book review	L. Addicks
Alaska Juneau Gold Mining Co.	656	Selling agencies	757
American Smelting & Refining Co.	608	World's production of	837
American Zinc, Lead & Smelting Co.	608	Copper Refining, book review	L. Addicks
Anacosta Copper Mining Co.	850	Corning, F. G. North Star Mines	117
Burnes-King Development Co.	572	Cost of Mining	Editorial
Benguet Consolidated Mining Co.	572	Book review	J. R. Finlay
Bingham Mines Co.	572	Cost of the War	Editorial
Broken Hill Proprietary Co., Ltd.	311	Cotton rope for transmission	660
Bunker Hill & Sullivan Mining & Concentrating Co.	850	Cottrell processes	495
Butte & Superior Mining Co.	850	Cox, G. H., C. L. Duke, and G. A. Muehlenberg	Field Methods in Petroleum Geology, book review
Callahan Zinc-Lead Co.	608	Craig, E. K. New type of oil-fired assay-furnace	184
Calumet & Hecla Mining Co.	607	Crampton, T. H. M. Silver Horn district, near Pioche, Nevada	
Camp Bird, Ltd.	731	Craze for mere bigness	Editorial
Central Eureka Mining Co.	818	Creative Chemistry, book review	E. E. Slosson
Champion Reef Gold Mining Co. of India	607	Credulity and the nitrate deposits	Editorial
Chief Consolidated Mining Co.	311	Crismon, G. W., obituary	512
Daly West Mining Co.	818	Crocker, W.	Prospecting
Davis-Daly Copper Co.	312	Cunningham, T. W. Oxy-acetylene welding and cutting	
De Beers Consolidated Mines, Ltd.	478	Curle, J. H.	
El Oro Mining & Railway Co.	478	Ditto This World of Ours, book review	441, 479
Franklin Mining Co.	656	Cutting metal with a steel disc	A. W. Allen
Goldfield Consolidated Mines Co.	572	Cyanide notes	Algernon Del Mar
Hecla Mining Co.	572	Solutions, de-aeration of	H. A. White
Hedley Gold Mining Co., Ltd.	818	Vats, regaining	
Hollinger Consolidated Gold Mines Co.	572		
Inspiration Consolidated Copper Co.	731		

	Page		Page
D		Editorial:	
Daly West Mining Co., company report	818	Oxy-acetylene welding and cutting	411
Davis, C. W. Radio-activity and some practical applications	229	Panama tolls dispute	380
Davis, F. P. Prospecting	740	Portland convention	517
Davis, J. A. and J. Gross. Recovery of gold from black sand	504	Position of silver	37
Davis-Daly Copper Co., report	312	Power projects	77
De-aeration of cyanide solutions	430	Presidency and journalism	279
Dean, R. S. Theory of flotation	291	Price of silver	279
Deane, E. C. Nevada Consolidated	413	Professional advice from the Bureau of Mines	801
De Beers Consolidated Mines, Ltd.	478	Prospecting	800
Deep mining on the Rand	335	Quiet times	867
Defence of Minerals Separation	89	Railroad problem	771
Definition of "concentrator"	352	Reparations	179
De Kalb, Courtenay. Metallurgical methods at Rio Tinto	185	Reporting a convention	588
Ditto. Pyrite in the Huelva district, Spain	125	Revision of the mining law	830
Del Mar, Algernon. Cyanide notes	810	Shut-down	484
Ditto. Rod mill	384	Silver and the Pittman Act	443
Denny, G. A.	398	Silver in prehistoric times	446
Destructible power resources	700	Simplicity in metallurgical planning	831
Development of vibrating screen	419	Taxation of mines	317
B. A. Mitchell and G. B. Rosenblatt	419	Transactions of the Institute	411, 587
A. M. Pontie	397	Transportation by motor-truck	280
Diamonds, slump in	611	Treaty with Colombia	555
Domestic and foreign supply of nitrate	249	Valuation of mines	379, 486
Drake, Francis. Coloring of glass	896	Vanderlip concession	76
Dredging in the Klondike	494	Ventilation and miners' phthisis	770
Drill-steel	488	Zinc industry	519
Drumheller, D. M., Jr. Tidewater mine	423		
E		Educating v. drop-forging	W. H. Coghill, 160
Easton, Stanley A.	865	Ditto	L. O. Howard, 285
Economic aspect of economic geology		Education for miners	Editorial, 772
Interests	C. A. Porter, 161	Of engineers	Editorial, 318
Situation in Mexico	Amigo, 41	Ditto	A. Locke, 521
Editorial:	266	Of a mining engineer	W. S. Weeks, 321
Alaska Juneau	623	Ellers v. Guggenheims	7, 63, 166, 199, 226, 264, 377, 396
American industry in the War	554	Ditto	Editorial, 1, 2, 443, 517
An all-round engineer	737	Electric Furnace, book review	H. Moissan, 609
Another apex decision	463	Furnace practice at Treadwell	W. E. Cahill, 535
Bain's appointment	38	Shovels	660
Blue-sky laws	465	Electric Welding, book review	E. Vail, 732
Broad-lode hypothesis	37	Electricity in coal mines	228
Business expansion abroad	518	Electrolytic Deposition and Hydrometallurgy of Zinc, book review	O. C. Ralston, 309
Colorado School of Mines	247, 552	Zinc refining	O. C. Ralston, 352
Company meeting	699	Electrolytic Zinc Co.	767
Conditions in Mexico	485	Elementary facts about oil	P. B. McDonald, 286
Conkling v. Silver King Coalition	349	Ellis, C., and J. V. Meigs	Gasoline and Other
Copper	348	Motor Fuels, book review	732
Cost of mining	78	El Oro Mining & Railway Co.	478
Cost of the War	623	Emminger, W. G.	Sampling in a mill, 152
Craze for mere bigness	664	Emmons, W. H. Geology of Petroleum, book review	609
Credulity and the nitrate deposits	589	Enberg, J. O. Technical practice in the Philippines	670
Destructible power resources	700	Engineer, an all-round	Editorial, 737
Domestic and foreign supply of nitrate	249	Education of a mining	W. S. Weeks, 321
Education for miners	772	Engineering Council of Utah	399
Education of engineers	318	Engineering Draughtsman, book review	E. Rowarth, 109
Ellers v. Guggenheims	1, 2, 443, 517	Engineering Electricity, book review	R. G. Hudson, 33
Flotation litigation	115	Engineering Foundation	Alfred D. Flinn, 86
Future of mining	444	Engineers, education of	Editorial, 318
German reparations	700	Ditto	A. Locke, 521
Guggenheims and the smelting industry	179	Everit, R. S.	Prospecting, 41
Hold fast and look forward	3	Explosives, handling of	Permissible, 96
How many hours	147	Export Packing, book review	C. C. Martin, 609
Industrial research	349	Ex-soldiers and prospecting	D. C. Simpson, 117
Institute affairs	214, 622	Eye, C. M.	Packing for export, 255
Institute as a publisher	116		
Institute magazine	736	F	
Institute membership and professional status	248	Fairchild, D. H.	Colorado School of Mines, 413
Institute transactions	411, 587	Fairhaven silver-lead district, Alaska	L. A. Levensaler, 195
International finance	216	Fernie, W., obituary	795
Irish question	146	Field Methods in Petroleum Geology, book review	G. H. Cox, C. L. Duke, and G. A. Muthlenburg, 610
Japanese problem	832	Filter, an ingenious	A. T. Fry, 266
Lead salts and plagiarism	215	Finance, international	Editorial, 216
Licensing of engineers	319	Financial Engineering, book review	O. B. Goldman, 658
Mexican affairs	830	Finch, J. K.	Topographic Maps and Sketch Mapping, book review, 33
Mining of quicksilver	553	Finlay, J. R.	Cost of Mining, book review, 109
Mr. Bain's appointment	38	Fire hazards at mines	191
New methods in geology	588	Fitch, Walter, Jr., Co.	Chief Consolidated shaft, 741
Nice point	319	Flin Flon mine	541
Noble beneficiation	114	Flinn, Alfred D.	Engineering Foundation, 86
Outlook for domestic silver	867		

K	Page	Metallurgical methods at Rio Tinto	Page
Kantishna mining district, Alaska	J. A. Haney 881	Courtenay De Kalb	185
Keith, Frank Allen, obituary	826	Ditto	L. S. Ropes 638
Kennecott Copper Corporation, company report	818	Ditto	G. D. Van Arsdale 451
King, A.	Lead salts in cyanide practice 803	Operations of the Judge Mining & Smelting Co.	A. B. Parsons 153
Klondike, dredging in the	494	Planning, simplicity in	Editorial 831
Knapp, S. A.	Prospecting 742	Method of calculating the average value of placer ground	Janshi Sen 704
Knox, H. H.	Institute affairs 323	Of recording geology in development work	C. E. Wuench 233
Koering process	T. F. O'Brien 523		Editorial 830
L		Mexican affairs	Metal production 360
Labor economics	H. L. Turner 413	Oil production	467
Labor's Crisis, book review	Sigmund Mendelsohn 309	Mexican Properties and Securities, Handbook of, book review	109
Lake Shore Mines, Ltd.	478	Mexico, conditions in	Editorial 485
Lancaster, A., obituary	795	Economic situation in	266
La Rose Mines, Ltd., company report	572	Mining opportunities in northern	707
Lawrence, B. B., obituary	208	Reconstruction in	501
Laws affecting oil exploitation in Mexico	C. A. Grabill 635	Miami Copper Co., company report	731
Lead, book review	J. A. Smythe 33	Miller, Hugo W.	Silver as money 39
Lead mining in Western Australia	196	Mine car compressor, portable	660
Poisoning	162	Car recorder, automatic	390
Poisoning, cause and control of	W. S. Slemmons 427	Timbers, treatment of	336
Salts and plagiarism	Editorial 215	Mineral resources of Queensland	462
Salts in the cyanidation of silver ores	R. W. Perry 221	Minerals Separation Co.	377
Salts in cyanide practice	A. King 803	Defence	Alfred A. Cook 89
World's production of	886	Patents	Gilbert H. Montague 5
Lena Goldfields	392	Miners, education for	Editorial 772
Lenskole Gold Mining Co.	394	Mines, taxation of	Editorial 317
Levensaler, L. A.	Fairhaven silver-lead district, Alaska 195	Valuation of	Editorial 379, 486
Lewis, W. V.	Prospecting 739	Mining as a business	H. F. Bain 641
Leyner drill	G. E. Collins 871	Congress Journal	866
Licensing of engineers	297	Engineer, education of	W. S. Weeks 321
Ditto	Editorial 319	Engineer, status as a	F. C. Smith 251
Lincoln, Abraham	219	Engineers and the Institute	P. B. McDonald 254
Liquid air, blasting with	843	Future of	Editorial 444
Locke, A.	Education of engineers 521	In Alaska in 1920	163
Loco-tractor system	442, 461	In British Columbia during 1920	61
London silver market, the ways of the	R. P. Skinner 719	In Dutch Guiana	A. R. Rogers 151, 383
Loomis, Horace	Mining opportunities in northern Mexico 707	Ditto	T. F. Van Wagenen 5, 283, 488
Loring, W. J.	McFadden Bill 251	Law, proposed revision of	845
Louvred bin	N. L. Hall 88, 593	Law revision	Editorial 819
Ditto	W. M. Hutton 323	Ditto	Editorial 830
Lowery, R. T., obituary	795	Litigation and common sense	A. B. Parsons 813
Low-grade and complex ores in Colorado	263	Manual and Year Book, 1921, book review	609
Luckiesh, M.	Artificial Light, book review 852	Of quicksilver	Editorial 553
Ludlum, A. C.	Russian placer mining 806	On the Mother Lode of California	A. E. Rau Roesler 807
Lunt, H. F.	An interesting silver deposit 670	Opportunities in northern Mexico	Horace Loomis 707
Lynn Big Six Mining Co.	409	Mining Congress Journal	866
M		Mining Manual and Year Book, 1921, book review	609
MacDougall, F. H.	Thermodynamics and Chemistry, book review 732	Mint for China	292
Magnetic, are drill-bits	335	Mitchell, B. A., and G. B. Rosenblatt	Development of vibrating screen 419
Malaya tin experts	285	Modern Welding Methods, book review	V. W. Page 33
Tin in	13	Moisson H.	Electric Furnace, book review 609
Tin production	884	Molybdenum mine, the R. & S.	132
Manganese mining in Argentina	389	Monypenny, J. H. G.	Unstainable steel 463
Martin, C. C.	Export Packing, book review 609	Montague, Gilbert H.	Minerals Separation patents 5
Mason, F. H.	Book-reviewing 833	Moonshine power	R. H. Sanders 834
Ditto	Chilean nitrate and synthetic compounds 452	Morris, E.	Single-jack in Western Australia 152
McCormick, W. S., obituary	764	Mother Lode of California, mining on the	A. E. Rau Roesler 807
McDonald, P. B.	Elementary facts about oil 236	Motherwell, W.	Amalgamation in stamp-mills 383
Ditto	Mining engineers and the Institute 254	Motor-truck, transportation by	Editorial 280
Ditto	Slosson's Creative Chemistry 708	Mount Bischoff Tin Mining Co., company report	607
McFadden Bill	W. J. Loring 251	Mount Lyell Mining & Railway Co., company report	312
McIntyre Porcupine Mines, Ltd., company report	311	Mount Morgan Gold Mining Co., Ltd., company report	312
McKay, R. F.	Theory of Machines, book review 33	Mountain Copper Co.	433
Mechanical World Electrical Pocket Book for 1921, book review	686	Moyer, J. A.	Gasoline Automobiles, book review 852
Mechanical World Year Book for 1921, book review	658	Ditto, and C. H. Sampson	Practical Trade Mathematics, book review 33
Meigs, J. V., and C. Ellis	Gasoline and Other Motor Fuels, book review 732	Mt. Bischoff Tin Mining Co., company report	607
Mendelsohn, S.	Labor's Crisis, book review 309	Mysore Gold Mining Co., company report	607
Mercury, tariff on	431	N	
Merrick, M.	Hoover and single-jacking 80	Naething, F. S.	Black Range tin district of New Mexico 557
Metal market	31, 73, 107, 141, 175, 209, 243, 275, 307, 345, 375, 407, 438, 475, 513, 549, 582, 619, 654, 695, 730, 765, 796, 827, 861, 894	Natomas Mines of California, company report	572
		Natural gas, chlorination of	430
		Need of quantitative methods in applied geology	C. H. White 601
		Nest, E. M.	Prospecting 706

Nevada Consolidated	E. G. Dean.....	413	Peterson flotation cell		424

Cuts Power Bills and Increases Tonnage

*Typical of the
Remarkable Records
Made by the—*

MITCHELL

**ELECTRIC
VIBRATING**

SCREEN

*—Under a Big Variety
of Operating Conditions
Is the Following,
Secured Under Test:*

The material was crushed through $1\frac{1}{2}$ in. square holes, moisture 6.41 per cent, screen cloth used $\frac{1}{2}$ in. square holes.

The Mitchell steadily screened 65 tons an hour and eliminated 96.31 per cent of the undersize material! And the power consumption never exceeded the rate of $\frac{3}{8}$ H.P. per day.

The result of that test is fairly indicative of results being obtained by the Mitchell in classifying not only coke but coal, slag, crushed rock, sand, gravel, salt, sugar, fertilizer, rice and ore. The versatility of the Mitchell is one of its most striking characteristics.

We have an interesting compilation of figures on Mitchell Electric Vibrating Screen operation, which we shall gladly send you, together with an illustrated booklet, describing the Mitchell in detail. Write us!

"The Waugh Way Wins"

Napoleon and the "Ninety"

NAPOLEON was a little man, but in ability, in energy and in endurance he was a giant. He worked fast; he worked thoroughly; and he achieved amazingly big successes.

THE new Waugh "Ninety" drills are also small in size, but in ability, endurance and capacity for faster, better work, and big successes they are like Napoleon.

WHETHER you operate a coal mine, a metal mine, or a stone quarry, you will want one of the three Waugh "Nineties" on the job at once. There is a "Ninety" specially designed to fit your needs. Send for our new "Ninety" booklet today. It will interest you.

RUGGED CONVEYOR BELTS—

Backed by a Practical Knowledge of Mining Conditions.

Our success in building endurance into Conveyor Belts for exacting mine and mill use is the result of a long, first hand experience in the field.

A comprehensive knowledge of mine conveying problems enters into the planning and construction of every belt. The correct weight and kind of duck in the right number of plies, bonded with a tenacious rubber friction and protected by a wear-resisting rubber cover, results in a belt to suit a particular conveying condition.

You are enabled, by means of our conveniently located branches to put conveying problems up to our experts for competent advice and solution.

Traylor Talks

TRAYLOR Great Falls Type CONVERTER

Tuyere boxes with Williams connections can be detached without disturbing the Tuyere pipes. They save the lining.

Write for Data.

LOOKING back over centuries and contrasting present day mining, milling and smelting methods with those of Agricola's time creates a stimulating picture of progress.

Consider the modern Traylor Great Falls Type Converter with its record of exceptional economy and service—and then realize how few handicaps are now set in the way of profitable copper production.

Uniformly Satisfactory Service

That is the reason for the ever-increasing popularity of Ingersoll-Rand Class "PRE" Compressors. Wherever electric power is available, these direct-connected, motor-driven units are the eventual selection.

One instance is the 30-inch stroke compressor at the Arizona Copper Company, Clifton, Arizona. This one unit, shown above, has a piston displacement of 6587 cu. ft. per minute.

Mr. Cooper, Purchasing Agent of this property, stated in his letter of August 19, 1920:—

"This machine has given uniformly satisfactory service since it was installed in 1916, and we are well satisfied with the work it does."

Let our engineers discuss your compressed air problems with you. Meanwhile, send for Bulletin No. 3216 describing Class "PRE" Compressors.

Ingersoll-Rand

SHOVEL AND LOAD WITH "LITTLE TUGGERS"

Mucking or shoveling consumes 35 % to 45 % of the total mine working time.

Certainly here is the logical place for a labor saving method and the logical method is—

Shoveling and loading with a "Little Tugger" Hoist connected to a scoop or scraper.

The method is called "Slushing" and the outfit is called the "Little Tugger Slusher."

It is not an experiment but has been proved in the largest mining districts in the world.

The "Little Tugger Slusher" shovels, scrapes, and hauls the rock and loads it into the tramcar.

INCREASED TONNAGE

AERO BRAND CYANIDE

Economical: Low delivered cost, ease of handling this flaky product, and reduced time required for settling and filtering solutions (due to coagulating effect on slimes) result in large savings in the course of a year.

Efficient: Aero Brand Cyanide is being used successfully on the widest variety of gold and silver ores, from the simplest to the most complex, with extraction efficiencies equal to the highest.

Dependable: Shipments of Aero Brand Cyanide have always been made promptly, as needed, without disappointment to a customer in four years.

AMERICAN CYANAMID COMPANY

511 FIFTH AVENUE, NEW YORK

Since 1827

WHEN Joseph Dixon made the first successful "black lead" crucible, Dixon Crucibles have maintained a standard of efficiency and quality that has kept them in the lead. The accumulated knowledge of nearly a century of crucible manufacture is woven into the walls of every Dixon Crucible.

DIXON CRUCIBLES

FROM graphite mine to finished crucible, the entire process is in the hands of Dixon operatives many of whom have made the manufacture of Dixon Crucibles their life-work.

Each crucible that bears the name DIXON carries the endorsement of an organization which has been through every stage of crucible evolution.

**BARTLEY
Victory B-42
CRUCIBLES**

**Are the
Crucibles
You Use Equalling
the Victory B-42 Average of over 57 Heats?**

Fewer and fewer are the complaints about short-lived crucibles as more BARTLEY VICTORY B-42's are used.

Mixing, forming, shaping, burning by the Lawton Process—using only the finest Ceylon graphite, skilled operatives trained in this special system—these produce BARTLEY VICTORY B-42 CRUCIBLES.

Quality is built into every VICTORY B-42—they are made *to endure heat*—and the average of over 57 heats taken from the service records of 21 crucibles tells the tale.

YOU HAVE A RIGHT TO EXPECT BETTER CRUCIBLE
VALUE THAN YOU EVER THOUGHT POSSIBLE WHEN
YOU BUY BARTLEY VICTORY B-42. SPECIFY THEM
ON YOUR NEXT ORDER.

CRUCIBLES**

Exceedingly high-grade zinc, electrically deposited from a solution of the ore, has played a vital part in maintaining American Independence

Five 5800-KW. Synchronous Converters at Anaconda Copper Co., Great Falls, Mont.

Continuity of Operation

WHEN zinc is being electrically deposited the current must not stop or the zinc already deposited will begin to go back into solution and its deposition must be paid for all over again.

To insure maximum continuity of operation, specially designed G-E synchronous converters having a wide margin in capacity are used. These machines have a voltage

regulation to allow for the difference between starting and running voltage of the cells and the variation in temperature and density of the solutions.

This regulation is obtained by split pole converters, or by induction regulators or boosters in the alternating current circuit.

Our specialists will be pleased to study your requirements.

Dryers of Approved Design

The men responsible for the design and construction of Ruggles-Coles Dryers have made drying equipment and drying problems their life study.

They are specialists—concentrating their entire efforts on one particular subject—drying. They have fixed their aims towards one end—dryers of the highest degree of perfection and mechanical excellence.

Ruggles-Coles Dryers, made in eight standard types for drying with

direct heat, indirect heat or steam, are dryers of large capacity and low operating costs. They are representative of the efforts of these experts.

Ruggles-Coles Dryers are built for constant service. They combine the greatest thermal efficiency with the lowest maintenance charges and give complete satisfaction wherever they are installed.

Numerous repeat orders are conclusive proof of their merit.

Ruggles-Coles Engineering Company, 50 Church Street, New York City
Branch Offices: Newhouse Building, Salt Lake City; Old National Bank Building, Spokane

Produces friction losses
Prevents good galvanizing coatings
Clogs delicate apparatus

"NATIONAL" Welding-Scale FREE Pipe

Minimizes corrosive tendencies
Gives full working capacity
Minimizes friction losses
Good base for galvanizing coatings
No loose scale to clog apparatus

"NATIONAL" Welding-Scale FREE Pipe is made by a process whereby the heavy mill scale, or welding-scale, which forms during manufacture is removed, leaving the pipe surfaces clean and smooth. All "NATIONAL" butt-weld pipe (sizes $\frac{1}{2}$ to 3-inch) is made by this process.

Power to Take the Grade— Do You Get It?

The New **Exide** Battery IRONCLAD

How this new development in construction, radically different from that of any other battery, increases its already long life.

Four ribs of $2\frac{3}{4}$ inches, instead of the usual two of $1\frac{3}{4}$ inches, provide a much larger sediment space.

In the usual construction all plates rest on the same two ribs. In the new Exide construction, however, positive plates rest on one set of ribs and negative on another. By this means short-circuiting from sediment building upon the ribs is practically eliminated.

The plates are provided with feet which raise them above the level of the separators. Thus sediment may completely fill the space at the bottom without producing an internal short-circuit.

When you don't take the grade look for the reason in your battery. It may have plenty of power, but if you can't get enough of it at one time, your locomotive won't pull its load up the grade.

Your battery may be like a narrow-necked bottle. No matter how much is in it, only a little at a time can get out.

Replace such a battery with a rugged, long-lasting, highly efficient Exide-Ironclad. A mine locomotive equipped with an Exide-Ironclad will take any grade up to the limit of its tractive effort. It will haul and keep on hauling, late afternoon as well as early morning.

Regardless of your haulage conditions, it will pay you to install Exide-Ironclads in your battery locomotives. Write us today for our booklet—"FACTS." It is a text book on what a storage battery ought to be and ought to do.

INDIVIDUALITY

Impellers are
cast solid in
one piece

Cameron impellers are individually designed to suit the needs of your particular pumping problem.

They are machined to an accurate balance, eliminating vibration. All accessible surfaces are carefully polished and the interior is hand finished to reduce water friction.

After assembly, every pump is given a thorough test duplicating your operating conditions.

A Cameron installation means certainty of pumping satisfaction.

Technical Writing

BY

T. A. RICKARD

179 Pages

Price **\$1.50**

Cloth

AS editor of the MINING AND SCIENTIFIC PRESS, the author needs no further introduction.

'TECHNICAL WRITING' was prepared in response to popular demand after the last imprint of the author's first book on the subject, 'A Guide to Technical Writing' was exhausted.

The B. F. Goodrich Company, Akron, Ohio, write:

"We have found this book of great benefit in our chemical and development departments to the men who write reports."

An important feature of this book is the inclusion of 600 examples of faulty writing, with corrections. These examples are taken from manuscripts edited by the author. The correction of them is a practical method of instructing those desiring to improve their methods of literary expression.

WHY WAIT ANY LONGER IN ORDERING THIS USEFUL AND INSTRUCTIVE WORK ON THE ART OF CORRECT TECHNICAL WRITING.

Westinghouse

Motors for Every Mill Requirement

In many cases an ordinary motor can be applied to do the work, but a motor particularly designed for the application will do it better, will be more efficient, and will require less maintenance. Many such Westinghouse motors have been developed and standardized for the various operations in metallurgical plants.

Westinghouse Engineering Service is at your command to determine on the best motor drive for every process in your mill. Westinghouse Engineers will help you to reduce first cost, power costs, and costly mill interruptions.

A Pacific Redwood Pipe Line Carries Water to the City of Oroville, California

The illustration shows part of a 20-inch Pacific Machine-banded Redwood pipe-line which was laid in 1911. It supplies water for the city of Oroville and has given uninterrupted service since its installation.

Pacific Redwood pipe is unequalled for carrying water, acid or alkaline solutions. Its long life, satisfactory service and adaptability to extremes of climate have made it the standard wood pipe for mining use.

The cap broke at 6,200 pounds

THE Oxy-acetylene welded joint in this test length of pipe easily held a hydrostatic pressure of 6,200 pounds. At this high pressure the cap blew off, but the weld withstood the pressure without an indication of failure.

Prest-O-Lite

DISSOLVED ACETYLENE

The Universal Gas with The Universal Service

was of course used exclusively in making these welds.

This test proves again the fact that for permanency—for strength—for perfect welds—Prest-O-Lite is the surest choice.

Ask us all about Prest-O-Lite and the Nation-Wide Service of our forty plants and warehouses.

T. A. RICKARD, . . . Editor

AID to the mining industry of Mexico is promised by the government of President Obregon. It is proposed to reduce Federal taxes and freight-rates on the railroads, and also to annul laws restricting the importation of such materials as steel, powder, acids, and tools. The President has been in consultation with the Governors of the mining States, including Guanajuato, Zacatecas, and Durango, for the purpose of devising means to assist the operation of mines.

GOOD SENSE was shown by the employees of the Granby Consolidated company at Anyox by their voting, in the proportion of 750 to 175, to accept the new scale of wages offered by the company. The manager, Mr. H. S. Munroe, told the men definitely that the company could not continue operations on the present scale of wages, having regard to the fall in the price of copper, and would have to close the plant unless the proposed reduction, of 75 cents per shift, was accepted, this reduction to be revised three months hence. Both management and men have shown moderation and, we repeat, good sense.

BEFORE international commerce can be restored to anything like a healthy condition it will be necessary to stabilize international exchange. That can best be done if the League of Nations, now in session at Geneva, is successful in its efforts. The world is called upon to choose between solvency and armaments; eleven out of twelve European countries showed a deficit last year, but in most cases disarmament would convert the deficit into a surplus. Of the world's total expenditure, 20% goes to preparation for war, and the burden is not only exhausting the European nations economically but it threatens to destroy them politically.

PROPOSALS are heard for dropping sundry taxes that operate unfairly, or that are uneconomic in their incidence. The excess-profit tax is one, the zone-rate of postage is another. We would like to see the check-tax revived because it is one that would be paid by those who can afford to do so; but the best expedient undoubtedly is the sales-tax, which at 2% is estimated to yield \$3,000,000,000 per annum, and therefore would go far to produce the revenue needed. Another good tax would be one on applicants for Federal appointments, at the rate, say, of 2½% on the salary of the desired office.

This would save a lot of time and trouble at Washington, besides conserving paper, of which there is such lamentable wastage at this time.

SENATOR HENDERSON has introduced a bill for amending Section 2324, Revised Statutes, dealing with assessment work on mining claims, so that the final date may be changed from January 1 to July 1 each year. This is commendable because the present date falls in the very dead of winter, and, as many of our mining districts are in the mountains, the season coincides with heavy snow and other inclement conditions prejudicial to the performance of the annual labor required by law. Assessment work is usually, and not unwisely, postponed as much as possible; for a man does not spend his money until he has to. We hope Senator Henderson's successor or his present colleague from Nevada will continue the effort to legislate in this direction.

REFERRING to the petition of Mr. Eilers, reproduced elsewhere in this issue, it is curious what blunders of phraseology are made by lawyers. For example, mention is made of "Messrs. Daniel, Murry, Isaac, Sol and Simon Guggenheim", and one asks naturally whether the fourth in order was named Sol or Solomon, but four paragraphs later reference is made to "the said Solomon R. Guggenheim". There is no "said" Solomon R., although there is a Sol—and long may he shine! Again, later, a paragraph begins with a reference to "their policy of gambling in metals", which they "carried further". There has been no previous mention of "gambling", so it is not clear how it could be carried "further". Obviously, in the previous paragraph the lawyer should have characterized the method, there described, as 'gambling', by saying, for example, that the policy of selling for future delivery involved transactions that were essentially of a gambling character. The punctuation of these legal documents is lamentable; it would be better if commas were omitted altogether, as is done by some attorneys, rather than use them indiscriminately. For example: "The staggering losses to the Company to which I have made reference herein". Does he make reference to the 'company' or to the 'losses'? Again: "When I found myself and my fellow directors, who had actively attempted to assist me in opposing the Messrs. Guggenheim, eliminated from the directorate of the Company". All his fellow-directors were not "elim-

inated", only those that had been backing him in his opposition to the Guggenheims; the comma before 'who' should be deleted.

THIS country is not threatened with a panic, but we are in the midst of a period of financial and industrial depression; how long and how serious this period will be depends upon the level-headedness of the American people. "This is the time for sanity and courage, not for pessimism and doubt," declared Mr. Frank B. Anderson, president of the Bank of California, in a notable address delivered recently before the Commonwealth Club in San Francisco. Mr. Anderson analyzed the events leading to the present abnormal condition of business; he suggested four fundamental things that must be accomplished before the necessary readjustment will be possible. First, the existing Federal revenue laws must be repealed; these he characterized as destructive, unfair, and unsound. They discount initiative, tax fictitious profits, put a premium on waste and extravagance, and penalize economy. Second, the great undigested mass of Liberty bonds must be absorbed by legitimate investors; in other words, these bonds must find their way into safe-deposit boxes instead of being perpetually pledged and re-pledged as security for bank-loans. One-third of the Federal Reserve loans today are based on Liberty bonds. Third, labor must be liquidated; which is another way of saying wages must come down. The fair thing would be to delay the reduction in wages until retail prices have been lowered; but the sequence will probably be reversed. Fourth, ways must be devised for financing the purchase of our excess products by the rest of the world, which needs them so badly but which cannot cope with the handicap of unfavorable rates of exchange. To these might be added the need for restoring the normal volume of buying on the part of the American people. Following a period of unprecedented extravagance, which lasted for several years, we suddenly went to the opposite extreme six months ago. A revulsion against \$100 suits, \$20 shoes, and \$5 neckties swept like a wave over the country and the consumer stopped buying. Thrift is always beneficial, but any radical change is likely to be attended with disaster. The various phases of business in the country are too intricately interlocked to permit extreme stagnation in the retail markets without a sympathetic reaction in industry and finance. What is needed is confidence on the part of the consumer that he is getting fair treatment from the retailer. Today he is distrustful; his attitude will be changed only by convincing action on the part of the merchants. All these things, except the last, are in the process of solution today. We agree with Mr. Anderson when he says that "patience and the same common sense that has pulled us through emergencies in the past will do so again. We have bountiful harvests, we have 105 million people to be fed, clothed, and amused; we are under-built, not over-built as we have been when most of the past booms burst. There is a world of work to be done and therefore I believe that we shall escape the long period of depression that usually succeeds such periods of inflation."

Eilers v. Guggenheims

In this issue we publish the text, *verbatim et literatim*, of the petition filed by Mr. Karl Eilers for a writ of mandamus calling upon the American Smelting & Refining Company to give him access to the company's stock register. The reason, which is plainly stated, for these proceedings is to enable Mr. Eilers to address himself to the stockholders, said to number 19,000, for the purpose of requesting their support in an effort to oust the Guggenheim family from the control of the company's administration and more particularly to eject Mr. Simon Guggenheim from the presidency of the company. In justification of his action, and of the further action he intends to take, Mr. Eilers gives facts, with arguments based upon those facts. The affair will interest our readers keenly, for it affects the mining industry in a large way, the administration of the affairs of such a corporation as the American Smelting & Refining Company being a matter of direct concern to those engaged in mining operations all over the country. We confess at once that our sympathy goes to Mr. Eilers, because we know him to be a professional man of high character and an operating metallurgist of the first rank. Moreover, he speaks, as it were, for his father, the late Anton Eilers, the pioneer of lead smelting in the West and one of the worthies of American mining history, a man of the highest type. Mr. Karl Eilers has long been identified with the Smelting company and we find it not at all difficult to believe that he has a genuine pride in its past and feels a genuine anxiety over its future. In short, we assume that he is prompted by worthy motives. It is fair to remark that his continued holding of such a large block of stock shows his loyalty to the company. Whether the writ of mandamus will enable Mr. Eilers to obtain the names and addresses needed by him for his appeal to the stockholders, we do not know. Possibly, by legal devices, the Guggenheims may balk his efforts long enough to enable them to obtain all the proxies required to re-elect themselves at the next annual meeting in April, but it is quite certain that the exposure of the management by Mr. Eilers' petition will have decisive results in other ways. In the first place, it marks a deep cleavage across the administration. Mr. Judd Stewart died not long ago, and we regret to recall the fact. Likewise Mr. Brush is no more. It has been known for some time that the directorate was splitting into two factions, but so long as the trouble was not ventilated publicly there was a chance of its being adjusted. Obviously it has gone so far now that those in control will have to give an account of themselves. It should be possible for the stockholders to assert themselves by appointing a committee of inquiry, but probably it will be difficult to do so if the Guggenheims oppose such an investigation. The old question arises, are directors to be regarded as trustees for the stockholders or are they only privileged speculators? Next, is the president of a company the spokesman for the directorate or is he a high cockalorum without accountability to his fellow-directors? It is evident that the story of the Smelting company is like

that of other creations of high finance. First a group of clever men organize a private business, which, as soon as it becomes successful, is turned into a public corporation, on a capitalization that discounts future expansion; the stock goes to a premium; the insiders sell out, but remain in office and retain handsome official salaries, long after they have ceased to give the service for which the salary is supposed to compensate. The Guggenheims started with 300,000 shares, or nearly half the entire common stock of the company. By April 1919, according to the statement made by Mr. Eilers, they had sold all except 100 shares of their common stock, and owned only 201 shares of the preferred stock. The entire board of directors, outside Mr. Eilers and his family, held only 700 shares of common stock, out of 650,000. Now the question arises, whether the directors of a company should be chosen for their stockholdings or for their ability as managers and their worthiness as trustees? It is to be presumed that so long as the Guggenheim family owned nearly half the property, as expressed in shares, they were entitled to a predominant voice in the management, particularly if their dominance synchronized with the distribution of satisfactory dividends, but when they sold their stock and their decreased shareholdings synchronized with diminished dividends, it became proper to question the advisability of a change in the administration of the enterprise. To put it bluntly, would Mr. Simon Guggenheim be engaged as the chief of the enterprise on account of his knowledge of mining and metallurgy, or of the business relating thereto, on his own merits as a technician and financier? That is a debatable point. Similarly most of the brothers and nephews might not be picked by other people to manage a mining and smelting business of large dimensions. Mr. Daniel Guggenheim, before he started his various speculations outside the Smelting company, was a man whose ability and acumen would be sought and would be engaged at a large salary, but it is evident, from the data given by Mr. Eilers, that the Guggenheims have treated the Smelting company as a perquisite of the family. This might not have proved too expensive to the shareholders, even at the rate of a total of \$500,000 per Guggenheim in ten years, but the gambling in copper, up and down, selling first for future delivery on a rising market and then holding copper on a falling market, has entailed losses that are much less agreeable, particularly as they are mixed inextricably with private interests in copper-mining companies. The other transactions in which the duties of the Guggenheims as directors of the Smelting company clashed with their private speculations and promotions are likewise manifestations of a kind of dealing that unfortunately is all too common in 'big business' circles, and it deserves to be pilloried. We appreciate the humorous side of the letter to Mr. Simon, retorting upon the latter's demand for the resignation of Mr. Eilers by insisting upon the resignation of the ex-Senator, who, by the way, acquired that senatorship by means not altogether according to Hoyle, however conventional in political circles in Colorado. Our readers will be able to form their own opinion of the merits of the quarrel

by reading Mr. Eilers' petition; when the Guggenheims make a reply, we shall publish it promptly, but we presume that their legal response will be a demurrer and a general denial. The test may come at the annual meeting of stockholders in April. Meanwhile we hope, in the interest of clean business in mining, that Mr. Eilers will succeed in getting at the stock register, so as to make an appeal to his fellow-sufferers and bring the issue to a public test.

Hold Fast and Look Forward

These are days that call for a steadfast mind and a virile optimism. Only now are we feeling the effects of the readjustments that were bound to come as the aftermath of a great war. The liquidation of commodities, securities, and labor was inevitable. In other countries, more deeply engaged in the bloody struggle of the calamitous years, the sequel to the Armistice of 1918 was a realization of lives lost, of finances depleted, and of government disorganized. We missed the acuter phases of the immediate post-war period; indeed, our loss of manhood in battle was relatively small, our gain in wealth was enormous, and our government, even if it did not suit everybody, was never shaken. Even after our share of fighting came to an end we failed to face the inevitable reorganization of industry, which had been stimulated unhealthfully by the manufacture of everything needed, and some things not needed, for the campaign overseas. Wages continued abnormally high, the prices of commodities were maintained on a false level, the extravagance of our people as a whole resembled an orgy. We are now in the cold gray dawn of the morning after. The conditions obtaining during the last three years could not last, because they were unreal. During the last quarter of 1920 the play of economic forces became insistent and prices generally suffered a nearly perpendicular drop, causing the appearance of a collapse of the market for textiles, foodstuffs, and metals. Wages remained firm until the very end of the year, when notices of severe reduction began to be issued on every side. Turning to the industry in which our readers, with us, are particularly interested, it is a fact, of course, that many mines had to be closed down on account of the decreased price of the metals, notably copper and lead. No disposition was shown on the part of labor to accept lower wages, as might be thought logical in deference to the fact that wages had been advanced when metal prices were rising; therefore the owners of mines were compelled in many cases to suspend operations. The unwillingness of labor to meet the conditions caused by the depression in the metal market is intelligible on account of the fact that the high cost of living had not been abated to any considerable degree, the drop in wholesale prices having been disregarded by the middlemen and retailers. In short, profiteering, that is, inexcusably high prices prompted solely by greed, was still dominant. The consequence was a widespread feeling that the bottom had dropped out of everything and that a calamity was impending. This feeling was not shared by those who

were well informed and capable of intelligent retrospection. Some of our friends, scared by conditions that they ought to have anticipated, reminded us of an inland child that sees the tide go out, not understanding its meaning. The child sees the waters withdraw from the beach, the rocks bared, the seaweed exposed, the boats stranded, and thereupon imagines that the ocean is about to dry up. The ebb and flow of the tide is a phenomenon no more natural than the rise and fall of markets, which are as obedient to the law of supply and demand as are the waters of the sea to the moon's behest. The world of economics swings and balances on a thin edge between 'must have' and 'must sell'. A man needs not to be a Methuselah to recall similar apparently catastrophic, but actually normal, ups and downs in the prices of metals, for example. What if silver is selling at 60 cents, copper at 13, and lead at 5; did not silver sell for 46 cents in 1915, did not copper sell at 11 cents in 1911, and did not lead sell at 3 cents in 1908? There have been depressions before, many times, and they have been followed by revivals, have they not? The tide comes back as surely as it goes out; shall we imitate the ignorant child and boo-hoo because our little sand-castle is left high and dry for a while?

Why should we be depressed unduly, much less despair, at the temporary recession of our tide of industrial activity? There is much to encourage us at this time. During the past fiscal year our foreign trade reached a total value of over 13 billion dollars, of which \$5,238,621,000 represented imports and \$7,950,429,000 exports, our commerce overseas being three billion dollars more than it was in 1919; moreover, five billions of it was carried in American vessels as against only \$368,359,000 carried in American bottoms during the year before the War. Our population, according to the completed census, is 117 millions, in itself a splendid market for our products and a huge reservoir of productive energy if properly organized. There is nothing unexpected or mysterious in the present condition of business; it has been foretold repeatedly by intelligent observers; we had no reason to expect to escape a time of liquidation in commodities, securities, and labor; we can thank our stars and the Federal Reserve system that the unpleasant process can be effected nowadays without a financial panic. The unpleasantness of the process of deflation is due mainly to the effort of some elements in the community to escape their part of the readjustment, and the rebound to a healthy recovery will be delayed until they are compelled to participate. The business of this country since the beginning of the War has been on a false basis of profit rather than of cost, whereas sound business is built upon economy. Our part of the world, like the other part upon which some of us look with a much too complacent pity, needs to work harder and save more. Only honest labor and decent thrift can establish individual and national self-respect. The Government must set the example; it is idle for statesmen to preach economy so long as they condone Federal extravagance; they must make an earnest and concerted effort to stop

the reckless expenditure of Government bureaus and departments, such as is exhibited by duplication of offices, multiplication of office-holders, and unending petty expenditures that in the aggregate run into millions daily.

Another change that we need is a broader outlook. It is absurd to expect to export without importing; it is ridiculous to anticipate a generous market for our own products while planning to erect a high wall of tariffs; it is foolish to expect to be prosperous while chuckling over the insolvency of our customers. The parochial view must be replaced by a world view. Too many of our men of business continue to show symptoms of shell-shock; they are so afraid of what the laborer and the tax-gatherer will take from them that they are unable to look abroad and realize the extraordinary opportunities offered to American capital and American initiative in foreign lands. At a time when foreign exchange favors exploitation abroad and acts as a most effective check to importation from abroad they strive apparently to shut themselves within their own borders and wish to regard the United States as an island in space, instead of seeing that it is today the senior partner of all the nations and the big brother of all the peoples.

The members of the mining profession hardly need to be lectured in this way; they have a mind of wider angle; they have traveled too much to be attracted by the ideas that cling to the parish pump; they realize the opportunity offered to our country in world-wide mining enterprise in consequence of the position of the United States as the creditor nation of the present epoch. Let us take a hint from the example of the English, who, when their country occupied a position of similar financial vantage, went forth into distant lands and sowed the seeds of a great commerce by starting mining exploration and exploitation in every corner of the earth. We have the capital to do it and the engineers that know how to do it. And now is the appointed time; for now is the time to buy prospects cheaply, especially in Mexico, where order has been restored and a new government welcomes foreign participation in genuine development. The prices of the metals are low, and therefore mines are cheaper than they will be when the metal market recovers. It is sure to recover soon, for civilization is built on a structure of metal and the growth of material progress involves a constantly increasing consumption of iron and copper, of lead and zinc, besides a score of minor metallic elements. For a while production is reduced on account of the high cost of everything involved in the production, but the incorrigible ratio of supply and demand will assert itself in due course, and then will come a revival of mining from its temporary slump. Financial arrangements for giving credit to European buyers are inevitable; they are already under way. There exists a great lack of metals in the countries devastated by war. Our own domestic consumption never stops, but increases progressively. There will be a good market for the miner's harvest from underground. Cheer up, gentlemen of the mining industry. The year will end much better than it begins.

Minerals Separation Patents

The Editor:

Sir—Two points in your admirable editorial of December 4, 1920, entitled 'The Flotation Conference', may possibly mislead some readers who for years have relied upon your information and guidance in all matters relating to flotation and Minerals Separation:

First: Referring to the exchange of telegrams between Mr. Cook, counsel for Minerals Separation North American Corporation, and Mr. Ballot, its president, on the question whether Minerals Separation claim that "if a licensee uses first patent in suit after its expiration in 1923, and operation thereafter does not come under other patents, he must continue to pay royalties to us", to which Mr. Ballot replied that "we do not claim payment of royalty on the patent in suit or on any other patent at time of expiration, but we do claim royalty for any other unexpired patents", you state: "Mr. Montague expressed gratification at Mr. Ballot's telegram, characterizing it as 'magnificent' and more than justifying all the efforts made by the American Mining Congress, in behalf of flotation users". Most of your readers caught the significance of your quotation marks around the word "magnificent", and everyone who heard me at the Conference will recall that I promptly called Mr. Cook's attention to Article 5 of Minerals Separation's standard license agreement which provides that "the licensees shall not directly or indirectly during the continuance of this license nor at any time after the termination thereof, dispute or object to the validity of the letters patent within this license, or the novelty or utility of the inventions specified therein", and that I then told the Conference—notwithstanding Mr. Cook's interruptions, protesting that there had been enough talk from lawyers—that any licensee who used after 1923 the process of the first patent in suit would be obliged, because of this provision in his license agreement, to accept Minerals Separation's opinion as to whether such process was covered by any of the scores of other "letters patent within this license", and would be prevented from ever "disputing or objecting" to Minerals Separation's opinion on this subject, and that until Minerals Separation rescinded Article 5, Mr. Ballot's apparent concession was not "magnificent", nor even any concession at all; to all of which Mr. Cook replied that he would not answer that question now. Without this colloquy—which you allude to merely as "a further altercation between the lawyers"—some of your readers may miss the significance of your quotation marks around "magnificent", and may impute to me an

attitude regarding Mr. Ballot's telegram which is exactly opposite to my true attitude, and may fail to appreciate that I am exactly in accord with your subsequent remark to the Conference to the effect that "as to the 'magnificence' of Mr. Ballot's telegram, he (Mr. Rickard) thought that interpretation ridiculous".

Second: You state: "It needed no lawyer to see that the Minerals Separation company could not collect royalty on a patent after it had expired." Lest some of your readers assume that this is a truism, and that Minerals Separation concedes it, and that no one anywhere denies it, and that any licensee of Minerals Separation may confidently act upon it, I must inform you that, except for the anti-trust laws and the Federal Trade Commission law, there is nothing whatever to prevent the owner of a patented process from requiring an operator desiring to use the patented process during the 17-year period of the patent to pay royalties for 25 years, or 50 years, or 75 years, or, like Minerals Separation, for 17 years from the date of any patent it may acquire in the future, which practically means eternity. The reason is that such a contract, harsh though it be, if voluntarily entered into by any operator of sound mind is, except for the anti-trust laws and the Federal Trade Commission law, a valid contract, absolutely enforceable in law. This is exactly what Minerals Separation in its standard license agreement has actually done, and manifestly intends to continue to do, unless, as I confidently expect, the anti-trust laws and the Federal Trade Commission law are successfully invoked to frustrate Minerals Separation's intention and purpose and to invalidate this provision of its standard license agreements.

Both of the points above mentioned were comprehensively discussed in my paper before the Conference, which you printed in full on December 11, 1920. Knowing, however, how natural it is for your readers to attach to your editorials greater weight than they do to any contributed article, I hope that, to prevent perhaps disastrous misunderstanding on your readers' part, you will find space for this overlong letter.

GILBERT H. MONTAGUE.

New York, December 18, 1920.

Mining in Dutch Guiana

The Editor:

Sir—It is surprising—even in these days when gold has lost so much of its purchasing power—to see a region so rich in that metal as the three Guianas neglected. For there is a field close to the United States; quiet and

orderly politically; well connected with the rest of the world by steamships, cables, and wireless; healthy; of low altitude; producing within its own borders most if not all of the staple supplies required by the mining industry, and presenting by undeniable evidence mineral resources that have yielded richly in the past, and whose possibilities have yet scarcely been touched.

All this is particularly true of that part known popularly as Dutch Guiana and officially as the colony of Surinam. Here labor is cheap, docile, efficient, and obtainable under a contract system that eliminates all possibilities of strikes. In addition, the mining law is remarkably favorable for corporate operations on either a small or a large scale. Though within the tropics the country is healthy, and even salubrious for all who exercise reasonable temperance in eating and drinking, and wear clothing which experience has shown to be most suitable under the circumstances. Yellow fever and other tropical maladies are practically unknown. The death-rate—including natives—averages from year to year about 14 per 1000, a record equalled by comparatively few communities in any part of the world.

I have recently been studying the records of operations there by a well-known Western mining man of high standing and confess myself rather surprised at the results he has obtained. He has been operating on gold-bearing quartz during the last seven years. Beginning with a small outfit capable of crushing but 8 tons in 24 hours he has gradually enlarged this out of profits until at the present time his plant will treat 125 tons in the same time. During the interim he has crushed 60,000 tons, from which gold to the value of \$135,000 has been recovered and marketed, and by plate amalgamation only. His record on tailings indicates that his loss has been not less than \$1.50 per ton, of which at least 75% could have been saved by the installation of a cyanide system or concentrating machinery.

Now here is a demonstrated proposition that has been built up on its own profits, that is based upon an ore carrying \$3.37 in recoverable metal, and of which there are millions of tons in sight directly on the surface both on and off his claims, all available by the simplest methods of quarrying. No underground work, no water to fight. No hoisting. Yet Siberia seems to be more attractive. What is the reason? Is it political, or economical, or merely psychological?

THEO. F. VAN WAGENEN.

Denver, December 4.

Poor Zones and Enrichments

The Editor:

Sir—The re-opening of the Plymouth mine in Amador county, and the results, as recounted so concisely by W. J. Loring in your issue of November 27, should start others thinking. The policy of the Plymouth management, since the beginning of operations in 1911, has been an open and helpful one. The occurrence of poor zones along the Mother Lode in other counties of California has been frequent, resulting in many companies suspend-

ing operations in the past, while others have exercised better judgment and continued, benefiting thereby. The Plymouth found a poor zone for 600 ft. below the 2450-ft. level, followed by high-grade ore; the Empire had no ore between the 1300 and 2100-ft. levels; the North Star had about 600 ft. of barren vein below the 1200-ft. level; and the Central Eureka seemed to be exhausted at 3400 ft. during 1918, but sinking to 3700 ft. revealed another shoot, and now the company is disbursing regular dividends. Another splendid example is the Carson Hill, now the third largest gold-producer in California, and the result of Mr. Loring's experience. Considering past results and lacking their geologic deductions, we find praiseworthy work under way in re-opening the Allison Ranch, Idaho-Maryland, and Old Eureka mines, all old producers. The North Star is resuming work at its Massachusetts and New York claims, closed years ago presumably through the usual barren zone; also the old Murchie mine near Nevada City. Note how the Tonopah Belmont resuscitated the old Shawmut mine. Apart from abnormal conditions, what is the matter with the Bunker Hill, Fremont, Amador (Original Amador), South Eureka, Oneida, Gwin, Black Oak, Utica, and others? Cannot more capital be raised to go ahead with these mines? All are fully equipped. At Sierra City is another instance: the Sierra Buttes mine yielded gold worth \$17,000,000 to a British company between 1870 and 1905, but save for spasmodic exploration and milling little has been done since. Nearly all mining was done through nine tunnels. I was told recently that geologic conditions have not changed, and that a wide vein remains, although of low value. The veins are quartz fissures with a greenstone and serpentine foot-wall, and a quartz-porphyry hanging wall. It is a pity that a modern 40-stamp mill and cyanide plant, such as on the Sierra Buttes, is left to the mercy of the elements, snow having already caved part of the roof. While on this topic, it is not out of place to draw attention to the bulletins recently published by the State Mining Bureau at San Francisco. I refer to 'Mines and Mineral Resources of Nevada, Plumas, and Sierra Counties', three separate volumes, compiled by Errol MacBoyle after a personal inspection of those regions. They are of great value. My work here has necessitated a close study of these bulletins, and I am surprised that so many apparently worthy mines are idle. There are also a number of drift-gravel properties that should demand attention. Exploration companies would do well to have copies of these reports on file. Perhaps they know all about the counties mentioned, yet something worth-while may have escaped their attention. It is to be hoped that when conditions improve, genuine investigation will be resumed in California. Mr. Loring has given a most practical hint; let others profit by it.

New York, December 10.

EMERY is mined at Naxos, in Greece, 9000 tons being the output in 1919.

Karl Eilers v. Guggenheims

Petition of Karl Eilers for a Writ of Mandamus Requiring the American Smelting & Refining Co. to Give Him Access to the Stock Register of the Company

SUPREME COURT, NEW YORK COUNTY

In the matter of the application of Karl Eilers for a writ of mandamus against American Smelting & Refining Company and David A. Crockett.

Sirs:

Please take notice that upon the annexed petition of Karl Eilers duly verified the 11th day of December, 1920, the undersigned will move this Court, at a Special Term Part I thereof, to be held at the County Court House in the Borough of Manhattan, The City of New York, on the 20th day of December, 1920 at 10.15 o'clock in the forenoon or as soon thereafter as Counsel can be heard, for a peremptory writ of mandamus under the rules of this Court, directed to the above named American Smelting & Refining Company and David A. Crockett, requiring the said American Smelting & Refining Company and David A. Crockett thereafter forthwith to permit the said Karl Eilers, his agents, accountants and servants, to inspect the stock book of the American Smelting & Refining Company and to make extracts therefrom, and for such other and further relief in the premises as may be just. Dated, New York December 11th, 1920.

WILLIAM U. GOODBODY,
Attorney for Petitioner.

To: American Smelting & Refining Company
David A. Crockett, Esq.,
William F. Schneider, Esq., Clerk of County of New York.

NEW YORK SUPREME COURT, NEW YORK COUNTY

In the matter of the application of Karl Eilers for a writ of mandamus against American Smelting & Refining Company and David A. Crockett.

To Special Term, Part I, of the Supreme Court of the State of New York for the County of New York:

The petition of Karl Eilers respectfully shows and alleges:

FIRST: That your petitioner resides at Sea Cliff, Long Island, New York.

SECOND: That American Smelting & Refining Company is a corporation organized and existing under and pursuant to the laws of the State of New Jersey. Said Company was incorporated on the 4th day of April, 1899. It has an authorized capital of \$115,000,000, represented by 500,000 shares of preferred stock and 650,000 shares of common stock. To the best of my knowledge and belief all of said preferred stock is issued and outstanding, and of said common stock, 609,980 shares are issued and outstanding.

THIRD: I have been since the incorporation of said

Company, and am now the owner of 210 shares of its preferred stock. I have been since 1916 and am now the owner of 17 shares of its common stock. I am also the owner of 200 shares of the preferred stock of said Company which I acquired from the Estate of Franz Fohr, who died July 27th, 1919, but which stock has not yet been transferred to my name by the Executor of such Estate.

As one of the three co-executors of the Estate of my father, Anton Eilers who was one of the founders of said Company, I am the holder and owner of 2170 shares of its preferred stock. In this stock I am beneficially interested.

Other members of my family whom I represent are holders and owners of preferred stock of said Company; their holdings aggregate 941 shares.

In my personal and representative capacities my total holdings are 3536 shares. For many years prior to the last annual meeting of the Company, which was held on the 7th day of April, 1920, I was a director and latterly Senior Vice-President of said Company.

FOURTH: The American Smelting & Refining Company is not a monied or railroad corporation and has offices for the transaction of its business in this State and within the County of New York, to wit: at No. 120 Broadway, Manhattan, New York City, and another office for the transaction of such business, and particularly for the transfer of its securities, at No. 149 Broadway, Manhattan, New York City.

I am informed and believe that said corporation keeps at its said office at No. 149 Broadway, New York City, a book known as a stock book containing the names, alphabetically arranged, of all persons who are stockholders of the corporation, showing their places of residence, the number of shares of stock held by them respectively, the time when they respectively became owners thereof and the amount paid thereon, and that said stock book is in charge of one D. A. Crockett, who is known as the "Transfer Agent" of said Company.

FIFTH: That on the 11th day of December, 1920, during business hours, to wit, at 11:30 A.M., I went to the said office of the said Transfer Agent of the American Smelting & Refining Company at No. 149 Broadway, New York City, and being then a stockholder of record of such corporation for at least six months immediately preceding such time, made a demand upon the said corporation and upon the said D. A. Crockett for an inspection of said stock book and for the opportunity to make extracts therefrom.

I am informed and believe that in March, 1920, said stock book contained the names of about 19,000 persons

who were then stockholders of said corporation and I believe that the number of names has not materially diminished since that time.

At the time I made such demand said corporation and said D. A. Crockett, the Transfer Agent thereof, wrongfully and in violation of Section 33 of Chapter 61 of the Laws of 1909 (New York), known as "The Stock Corporation Law," refused to allow said stock book to be inspected by me or to allow me or my duly accredited agents and attorneys to make extracts therefrom.

SIXTH: The next regular annual meeting of said corporation will occur in the month of April, 1921.

The purpose for which I desire to inspect and make extracts from the stock book of said corporation is to enable me to communicate with other stockholders of said corporation in order to consult with them relative to effecting a change in the management of the affairs of said corporation by the election at said annual meeting of a new Board of Directors for said corporation. To that end it is necessary that I place myself in communication with stockholders whose holdings of stock are as large or nearly as large as my own, for the purpose of forming a Stockholders' Committee, and then to communicate with other stockholders to secure proxies, or the direct votes of stockholders, for the election of persons as directors of said corporation other than those now holding office as directors. I can accomplish this only if given free access to the stock book of said Company.

I am moved to do this because of an honest belief that a change in management is vitally necessary for the well-being of said corporation. I desire the interests of said corporation promoted that I and those whom I represent may as stockholders be thereby benefited. Also because of the association of my father with said Company from its inception to his death, and my own association with said Company as employee, director and officer for over thirty-one years I feel a keen personal interest in said Company, and its well-being and development.

SEVENTH: From 1907 to 1920 I was a director of said Company. From 1916 to 1920 I was Vice-President of said Company. As a director and particularly as an officer of said Company, I had opportunity to observe the methods of its management and I was finally convinced that said Company has been for several years, and is now under the control of persons who dominate its affairs and under whose direction the Company is managed, not for the benefit of its stockholders or for the well-being of said Company, but for the purpose of furthering the personal and selfish ends of said persons and in disregard of the interests of said Company. I am convinced that such domination of the Company's affairs has resulted in retarding its development; to my personal knowledge the Company has been thereby directly caused losses aggregating millions of dollars. I am convinced that a continuance of such domination will further retard its development and entail further large losses to the Company. I am convinced that only by a change in the Board of Directors of said Company, can such domination of its affairs be ended.

In evidence of all of which I make the following statement of facts and circumstances upon the information gained by me during my association with said corporation as a director and officer.

The said corporation was organized in 1899, a consolidation of various smelting interests being thus effected; the smelting concerns entering the corporation receiving cash or stock of the corporation in exchange for their assets. At that time the Messrs. Daniel, Murry, Isaac, Sol and Simon Guggenheim, owners of certain smelting concerns were invited to become stockholders in said corporation; to sell their smelting interests to the corporation in exchange for its stock. The said Messrs. Guggenheim refused such proposition.

In 1901 the said corporation had shown itself to be in every way successful, and thereupon the Messrs. Guggenheim proposed to place their smelting interests within the corporation in exchange for its corporate stock. They insisted that they be admitted to the corporation and their proposal being accepted, they thus secured approximately 300,000 shares of the corporate stock (\$30,000,000 par value).

The Messrs. Guggenheim at once demanded representation on the Company's Board of Directors, and were successful in placing upon said Board Mr. Daniel Guggenheim as Chairman and Messrs. Murry, Isaac and Sol Guggenheim as members.

In or about 1907 the holdings of stock of the Messrs. Guggenheim, except for a very small portion, were sold by them. As I am informed and believe such sale was forced upon the Messrs. Guggenheim by reason of business reverses. From that time the Messrs. Guggenheim apparently ceased to regard the interests of the corporation and sought to employ it solely to serve their own ends. In spite of the fact that they no longer held stock in the corporation to an amount which gave them any substantial interest in its affairs they continued their membership on its Board of Directors and insisted upon dominating that Board and the affairs of the corporation.

Early in 1919 the said Solomon R. Guggenheim resigned from the Board; the said Messrs. Isaac, Daniel and Murry Guggenheim remained upon the Board, and the said Simon Guggenheim became President of the Company. By that time the Messrs. Guggenheim had so perfected their domination of the Company that they did and could with confidence presume the acquiescence of a majority of the directors. When in January of that year they decided that Mr. Simon Guggenheim should become President of the Company and Mr. Daniel Guggenheim, the then President, announced this in a circular letter to the stockholders as "the expressed wish of the Board of Directors". The Board of Directors had not in fact been notified, much less consulted, in respect of the proposed change in the presidency of the Company; they had been given no opportunity to express any wish in the matter. The Board met the expressed wish of the Messrs. Guggenheim and elected Mr. Simon Guggenheim their President. The situation in the Company under Mr. Simon Guggenheim was well stated by one of my

fellow directors—"Simon snaps the whip and all the rest have to jump".

During all the time aforesaid, from 1907 to 1920 while I was a director and officer of said corporation I found it impossible for me, or any of my associates on the Board of Directors to secure the adoption of any plan for the operation of the Company against the opposition of the Messrs. Guggenheim. The majority of the members of the Board of Directors were controlled absolutely by the orders of the Messrs. Guggenheim and were in fact merely dummies representing the Guggenheim interests. This was true to such an extent that on one occasion when I protested to a member of the Board for his obedience to all mandates of Mr. Simon Guggenheim, he replied to me: "I don't like to do this, but what are you going to do when you are working for a man".

About 1910 the Board of Directors on the orders of the Messrs. Guggenheim and over the protest of myself and Mr. Morse, adopted a resolution that the salaries of officers, directors and employees should be fixed by a so-called Salary Committee, of which Mr. Murry Guggenheim was then made Chairman. At this time Mr. Daniel Guggenheim and Mr. Sol Guggenheim had been drawing salaries ranging from \$25,000 to \$50,000 per annum while they were devoting almost their entire time and attention to business matters not connected with the affairs of the Company. This was a cause of irritation among the other officers and directors. From that time the Board of Directors had no power to fix the salaries of the officers and directors of the Company, and the Board of Directors could obtain no information from the Messrs. Guggenheim or from those directors who acted in concert with them as to the amount paid to the officers and directors of the Company. I believe the real purpose of this arrangement to have been to enable the Messrs. Guggenheim to perfect and continue their influence over the directors; by means of this Salary Committee controlled by the Messrs. Guggenheim they could by increases and decreases in salary reward the obedient and punish the recalcitrant.

About 1910 Mr. Newhouse and Mr. Stewart reported an opportunity to enter the business of tin mining in Bolivia. The Company with the consent of the Messrs. Guggenheim, expended considerable money in a thorough investigation of this proposition. Upon the report of such investigation coming in, the Messrs. Guggenheim opposed any action relative to the proposition. Thereafter the sons of Messrs. Murry and Daniel Guggenheim representing Guggenheim Brothers, the Messrs. Guggenheim's co-partnership, were permitted to examine the report of the investigation on file with this Company, and thereupon Guggenheim Brothers sent representatives to Bolivia and have since engaged in large tin mining operations there. A demand by certain of the directors of the Company that it be allowed to share in such operations was refused by the Messrs. Guggenheim.

In 1919 Mr. Guess, managing director of mines for the Company, advised the Board of Directors that he had secured an opportunity to purchase a one-fourth interest

in the Premier Silver & Gold Mine in British Columbia at a price which would be most advantageous to the Company. A majority of the members of the Executive Committee of the Company to which the matter was referred were in favor of accepting this offer but Mr. Simon Guggenheim, a member of the Executive Committee, and Mr. Murry Guggenheim, a director, objected and opposed its acceptance. It later developed that the sons of Messrs. Murry and Daniel Guggenheim representing Guggenheim Brothers, desired to purchase one-half of such one-fourth interest. Upon an arrangement being effected which permitted Guggenheim Brothers to purchase one-half of said one-fourth interest, Messrs. Simon and Murry Guggenheim withdrew their objection to a purchase by the Company of the remaining half of such one-fourth interest.

The business of the Company is the purchase and smelting of ores of various kinds, and the sale of metals, copper, lead, silver, etc. thus produced. The prices paid by the Company for the various ores are based on the current New York quotations for the metals in such ores. The Company learned from bitter experience that if losses from fluctuations in the prices of metals were to be avoided, metals must be sold as fast as smelted and refined, and only to the quantity smelted and refined; no sales substantially in advance of production could be made. Prior to the domination of the Company by the Guggenheim interests this was the established policy of the Company.

In respect of sales of copper, this policy was abandoned so soon as the Messrs. Guggenheim secured predominating influence in the Company's affairs. In copper, under the direction of Mr. Murry Guggenheim, futures were dealt in by the Company; that is to say, the Company made sales for future delivery against ore to be purchased and copper to be produced therefrom. I believe the Messrs. Guggenheim were influenced to this change in policy in respect of copper sales by their interests in various copper companies. I know that through the Messrs. Guggenheim contracts were entered into making this Company selling agent for such copper companies. In 1915 I was informed by a Mr. Willard Morse, one of the Company's directors, that as the result of this method of selling for future delivery the Company was losing on copper at the rate of \$1,000,000 per year. A statement prepared by a Mr. F. W. Hills, the Comptroller of the Company, disclosed losses from this source for the seven years 1912-1919 to aggregate over \$5,000,000.

My fellow-directors, Mr. Morse, Mr. Brush, Mr. Newhouse, as well as myself, protested against this policy, but Mr. Murry Guggenheim insisted upon it and its continuance. Mr. Murry Guggenheim attempted to justify these losses upon the ground that the Company, through sales for future delivery, was enabled to retain the business of selling for the group of copper companies with which it had entered into the aforesaid contracts to act as sales agent; that this Company could thereby retain 1% selling commission from such copper companies. Had this Company abandoned the policy of selling for future

deliveries it would have reduced its losses from fluctuations in the price of copper to a minimum and I am convinced it could have retained the agreements with the copper companies. As I am informed and believe the more important of those companies were controlled by the Messrs. Guggenheim through stock ownership; and the abandonment of the policy of selling for future deliveries would have prevented very large losses from fluctuations in the price of copper to those companies as well as to this Company. The copper companies to which I refer are the Utah, Nevada Consolidated, Kennecott, Braden, Chino and Ray.

In 1920 the Messrs. Guggenheim carried their policy of gambling in metals further. At this time the copper market showed a tendency toward a sharp decline in prices. Having made the mistake of selling for future delivery in a rising market, the Messrs. Guggenheim now withheld copper from sale in a falling market. In April, 1920, as the result of this policy, the Company had on hand approximately 160,000 tons of refined copper. In the meantime the price of copper had declined at least 5 cents per pound (\$100 per ton) with a consequent loss, traceable to the Guggenheim influence, of at least \$15,000,000 to the stockholders of the companies concerned, the copper companies and this Company.

In the Company's purchase and sales of silver and lead, Mr. Brush continued to follow the policy, previously followed in sales of copper, of selling currently instead of for future delivery. The fluctuation of prices in the lead market during the period 1914-1918 were similar in percentage to the fluctuation of prices in the copper market and the Company's tonnage in lead was greater by far than its own tonnage in copper. Under Mr. Brush's policy the Company made a profit on its transactions in silver, and the Company's losses from fluctuation in prices of lead were held down to the comparatively small sum of \$465,060.71 for the period 1904-1918. For the same period, under Mr. Murry Guggenheim's policy, the Company's losses in sales of copper, according to a statement by Mr. F. W. Hills, amounted to \$4,638,934.85. The Messrs. Guggenheim were not so largely interested in silver or lead producing companies as in copper companies.

Of the directors of the company, Messrs. Prosser, Newhouse, Stewart, Morse, McGowan and I were those who were outspoken in expressing their views relative to the business and policies of the company; Messrs. Prosser and Newhouse were more ready to yield to the opinions and directions of the Messrs. Guggenheim; Messrs. Stewart, Morse, McGowan and I were insistent in pressing our views irrespective of whether they were in accord with the opinions and decisions of the Messrs. Guggenheim.

The majority of the remaining directors of the Company were men dependent for their livelihood upon the salaries they received. These the Messrs. Guggenheim could control by fear of dismissal, and these directors did not venture actively to oppose the mandates of the Messrs. Guggenheim.

At the time when Mr. Simon Guggenheim was elected

President of the Company, Mr. Newhouse was made Chairman of the Board of Directors. It is significant that immediately after the annual meeting in April, 1920, when I was forced from the Board, to which I shall hereafter refer, Mr. Prosser was promoted to the position of Vice President and at the same time three new vice presidencies were created and three other directors were placed in those offices. The opposition of Messrs. Prosser and Newhouse was silenced by these promotions and the loyalty to the Messrs. Guggenheim of the three other directors secured by the same means.

Immediately after his election as President, Mr. Simon Guggenheim informed Messrs. Stewart and Morse that their services were no longer required, and demanded their resignations. Mr. Stewart ceased to be a director. I am informed that at this time Mr. Newhouse protested to Mr. Simon Guggenheim that he was going too far, and thereupon Mr. Morse was allowed to continue as a director of the company but in a position of no influence and at a greatly reduced salary. At this time Mr. McGowan declined to continue as a director of the company under Mr. Simon Guggenheim and resigned from the Board of Directors.

In March, 1920, a few days prior to the regular annual meeting of the stockholders of the Company, I received from Mr. Simon Guggenheim a letter informing me that because of the difference in our views relative to the management of the Company, I must sever my connection with the Company. In the next month (April) I failed of re-election as a director. I append as Exhibits A and B Mr. Simon Guggenheim's letter to me and my reply thereto.

With the ousting of Messrs. Stewart, McGowan and myself, and the shelving of Mr. Morse, directors who actively opposed the Messrs. Guggenheim, and the silencing by promotion to office of Messrs. Newhouse and Prosser, directors who had been rather active in their criticisms of the policies of the Messrs. Guggenheim, and with the loyalty of the three directors promoted to the office of Vice-President assured by such promotion, the Messrs. Guggenheim have disposed of any possible opposition on the part of the Board of Directors and have placed themselves in a position to control and manage the Company as they may see fit without fear of effective criticism by the Board. Re-election of the present Board will continue the Messrs. Guggenheim in such position of dominance; a position which in the past has resulted in the staggering losses to the Company to which I have made reference herein.

EIGHTH: I have stated that I am moved to the instant proceedings by the honest belief that it is necessary for the well-being of the Company that steps be taken to secure a change in the Company's management. I have herein set forth with some particularity matters concerning the present management as establishing ample grounds for such belief on my part and therewith the honesty of my motives. I am not acting as a disgruntled ex-director or officer seeking revenge for his removal or his own re-instatement. I am convinced and I submit I

have grounds for the conviction, that the interests of the stockholders demand that they be acquainted with the situation in their Company. Because of my long association with the Company and because of the number of shares owned and represented by me I consider that I am the logical person to move that the stockholders may be so informed and that I am in a manner morally obligated to do so. My own holdings in the Company, those owned and represented by me, also make it a matter of great importance, financially, to me that I secure a correction of the existing situation in the Company affairs. In this connection I invite attention to the statement of the number of shares of stock held by the directors of the Company in 1919 and 1920 as disclosed by my letter, Exhibit B, and by a statement hereto annexed, marked Exhibit C.

While a director and officer of the Company I did not take the action which I now propose for the reason that the dominance of the Guggenheim interests was a matter of development and reached its climax only just prior to my removal as a director and officer. Owing to the fact that I was absent from New York City engaged in business matters for the Company, I was not in a position to realize how successfully the Guggenheim interests were campaigning to secure control of the Company or to what extent such control had worked to the Company's injury. When I discovered the facts relative to these matters I hoped through my own influence and the influence of my fellow directors, Messrs. Prosser, Newhouse, Stewart, Morse and McGowan to secure a correction of the situation; I believed it better in the interests of the Company to attack this from the inside and it was only when I found myself and my fellow directors, who had actively attempted to assist me in opposing the Messrs. Guggenheim, eliminated from the directorate of the Company, that I realized the impossibility of successful opposition to the Messrs. Guggenheim unless by and through the assistance of the stockholders of the Company.

Wherefore your petitioner respectfully requests that a peremptory writ of mandamus issue directed to the defendants directing them to permit the petitioner and his agents, accountants and servants to inspect the stock book of the defendant American Smelting & Refining Company, and to make extracts therefrom.
Dated, New York, December 11th, 1920.

KARL EILERS,
Petitioner.

WILLIAM U. GOODBODY,
Attorney for Petitioner.

State of New York }
County of New York } ss.

Karl Eilers, being duly sworn, deposes and says: that he is the petitioner in the above entitled matter; that he has read and knows the contents of the foregoing petition, and that the same is true to his own knowledge except as to the matters therein stated to be alleged upon information and belief, and that as to those matters he believes it to be true.

KARL EILERS

Sworn to before me this
11th day of December, 1920.

AMERICAN SMELTING & REFINING CO.,
120 Broadway, New York.

Mr. Karl Eilers,
Vice President.

American Smelting & Refining Company,
120 Broadway, New York, N. Y.

My dear Mr. Eilers:

Shortly after I became President of the American Smelting & Refining Company, it became evident that you were not in sympathy with my administration.

I had hoped that time would work a change in your attitude, and bring about a better accord between us, but a year has gone by with no prospect of such a result. Our views differ so fundamentally and on so many questions, that we cannot, with advantage to the Company or in justice to either of us, continue to be longer associated in the management.

I have reached this conclusion with the deepest regret, because of our long association. The decision was reached after careful consideration, and I regard the step as being absolutely necessary for the welfare of the Company.

This letter is written that you may have an opportunity of yourself taking the initiative and tendering your resignation before the coming annual election on April 7th, if you so desire.

With assurance of personal regard and good will,

Respectfully yours,
(signed) S. GUGGENHEIM

EXHIBIT B

120 Broadway, New York City,

Hon. Simon Guggenheim,
President,

American Smelting & Refining Company,
Dear Sir:

I have your personal letter dated March 31st, which was delivered to me the next afternoon and which suggests that I should resign from the American Smelting & Refining Company for the sole reason that you and I are not in accord.

You are very right when you say that I have not been in sympathy with your administration. That is, perhaps, one of the strongest reasons why my continued connection with the company should be to its advantage. Since your brothers caused you to be made President, your views and mine as to the administration of the company have differed fundamentally, possibly because we represent different interests and may be working for different ends. My family and I are now among the largest stock-

holders and have held the stock from the company's beginning, and we have no interests of any kind adverse to the company. You and your family associates have disposed of practically all of the 300,000 shares which you had when you assumed control and now, unless as traders in and out of its stock, you have practically no stake whatever in the company and may not be free from adverse personal interests.

I find from the stock records that at the time of their last election our directors held stock in the company as follows:

Total stock held by directors	6089	1291
Total stock outstanding	500,000	650,000

Throughout your administration my views as to policy have systematically been overridden by you.

I disapprove of gambling in copper, as I have disapproved of the gambling in copper during the year 1912 to 1918, when it occasioned a loss to the company of five or more millions of dollars. I feel that that loss should be made good. I have disapproved of the payment to certain members of your family of sums aggregating at least \$500,000 each in salary and office facilities during the past ten years, without services rendered.

I have disapproved of the arbitrary manner in which you have failed to consult the directors of the company, men who, in many cases, have had far more experience than yourself, or, consulting them, have failed to give the slightest attention to their views.

From the time when your brothers treated the directors as puppets in order to bring about your election, you yourself seem to have regarded and treated them as puppets. One of our present directors summed up the matter correctly when he stated: "Simon snaps the whip and the rest all have to jump". Such a method of operation would be harmful under any circumstances, but when employed by one whose interest may not necessarily be that of the company, it becomes appallingly dangerous. Now I have not had to jump, and I do not propose to jump, and I will not resign.

I have disapproved of your vacillation, of your financial policy and your lack of any consistent operating and

extension policy, of your treatment of the company's valuable employees. I believe that you have been undermining the loyalty of the men and destroying the organization which should be the company's most valuable asset.

I have disapproved of the management being in the hands of those who have disposed of their stock interest and who have what should be competitive interests, of the failure in prosperous times to put aside proper funds for more difficult times, of the policy which has made it necessary to take up measures needful for the company through indirect and personal suggestions of a particular few, rather than through the company's regular organization.

I have viewed with alarm our unsatisfactory earnings and the decline of the market price of our stock during the period of your direction.

In requesting me to resign, it is evident that you, with at most a transitory interest in the company, have found my single minded zeal in the company's behalf inconvenient. If I could consult only my own personal convenience, I would be inclined to accede to your request. But I cannot forget that there are many matters that demand attention in the interest of the stockholders and that, as shown by the stock books at the time of the last election, I am one of the few directors who represent a substantial stock ownership and whose personal stake therein is so great as necessarily to make the company's prosperity their own first interest. Furthermore, as from length of service, I have become the company's senior Vice President and have devoted practically my entire life to its service and that of its predecessor, it is quite possible that I might be of more service and value to the stockholders than one otherwise similarly situated but without that training and experience.

I have desired, perhaps mistakenly, to preserve harmony in the company, in the hope that you might yield to advice or to evident result or lack of results, and soon might find other fields of activity more suitable for you, and the company thereby obtain the necessary change in management without the publicity and other disadvantages of a contest. As for those reasons I have up to this time made no effort to prevent it, it may be within your power for the time being to force my retirement from the Board. Nevertheless, I must most emphatically decline to resign, as I feel that it would be a betrayal of my duty to the stockholders voluntarily to abandon them, even for only a few days.

In so far as our views have not been in accord, as we both say that they have not been, the event seems to have proved that it would have been to the interest of the company and of all, perhaps, except yourself and yours, if my views and not yours had prevailed. It would seem obvious that under the circumstances the proper remedy would be your resignation and not mine. It is also obvious that the interests of the company and its stockholders require an immediate change in the management.

I therefore suggest that you should forthwith tender your resignation as President of the American Smelting

& Refining Company and should at once take steps to make up to the company, for the stockholders, the various losses which it wrongfully and unnecessarily suffered.

Yours Very Truly,
(signed) KARL EILERS

Tin in Malaya

Fifteen years ago Malaya produced over 60% of the world's tin; today the figure stands at less than 40%. In 1903 Bolivia was credited with under 10,000 tons; today that country is the second largest tin-producing country of the world and unofficial estimates give it 20 to 25% of the total output. Nigeria, whose output ten years ago was practically negligible, is returned in official statistics as producing in 1917 nearly 10,000 tons. The Malayan production in 1919 is given as 36,867 tons, compared with 50,000 tons five years before. Yet here is a rather curious circumstance. Taking official statistics for the years 1903, 1904, and 1905, and those 12 years later it is noted that the total output of ore has on the whole increased. The loss on Negri Sembilan output is more than offset by the gain in Pahang, while the loss on Selangor is easily cared for by the gain in Perak. The deduction is that although the percentage comparison of Malayan output with the world's total has fallen owing to greater production elsewhere, the actual production has considerably increased. Although production has been affected by cumulative years of war restrictions and hindrances and present figures do not indicate the real strength of Malayan ore production, there is sufficient ground for urging that the industry should be taken more

carefully into consideration. At present there is one large and well-known American mining company operating in the Federated Malay States. This firm is importing large quantities of material and sending out capable men as prospectors. Realizing that they must do more than mere surface mining to obtain results in the future and perhaps stimulated by the advent of the American company, already referred to, many of the local mining corporations are taking a keener interest in scientific mining and are preparing to go ahead on a much more thorough principle.—Commerce Reports.

Standardizing in Mining

Standardizing mining operations presents problems quite different from the problems of the manufacturer. Methods of a successful factory may be duplicated by copying its arrangement and equipment and following its production details; standardization can readily be applied to most manufacturing processes, especially if the article manufactured is produced in large quantities. Mining operations, on the other hand, are carried on under conditions that vary widely in different mines and even in the same mine. No two mines are alike and methods that prove efficient and economical in one mine are inefficient and uneconomical in another, where the formation and ore occurrence are of a different type. Standards to be effective must be specially worked out to meet the conditions of the particular mine in which they are employed, says Robert Linton, president of the North Butte Mining Co., in 'Mining and Metallurgy'.

It should be emphasized at the outset that any studies of standardization and efficiency should primarily be directed to helping the underground workman do his work more skilfully with less effort and less fatigue. It is an axiom in every line of industry that the most skilful workman is, as a rule, the workman who does his work with the greatest ease. The purpose should be to devise means for further development of skill, to make it possible for more men to possess it, to eliminate all avoidable delays and lost motion in the working organization, and thus enable them to do the maximum amount of work without injurious overexertion. Given good working conditions and a square deal, the average workman would rather feel that his day's work turns out something of benefit to his employer than not, and is willing to do his best if he knows his efforts are recognized and compensated for on a fair basis.

The miner was formerly a member of a highly specialized trade—skilled in the manipulation of drills and the use of explosives, familiar with varying kinds of rock, trained to observe anything and everything that affected the particular mining job on which he was employed. There are still many such skilled miners working underground, and every mine superintendent is on the lookout for them, but there are also many who do not possess this skill and who work much harder without accomplishing as much because their efforts are not utilized to the best advantage. Standardization of methods benefits such men particularly.

The Future of Copper

By Edwin C. Holden

The rapid change in copper prices during the past few months has made producers and consumers alike eager to look into the future. Prophecy is an extra-hazardous occupation, but in the case of copper a review of its record during and prior to the War and a consideration of present industrial conditions make some general deductions possible. In any event, the valuer of copper mines must make the attempt if he is to reach any clear-cut conclusion.

The record of the copper industry in recent years is summarized in the accompanying table compiled principally from the 'U. S. Mineral Resources' and modified as to foreign production by 'The Mineral Industry'.

matte, blister, refined, manufactured, and scrap copper; the stock is of new refined copper and is not to be confused with that far more important figure, the copper surplus, which includes blister and copper in all unconsumed forms, whether in the hands of producers or consumers.

Data on the copper surplus are only approximately obtainable. The normal surplus for the United States has been stated as about 400,000,000 to 500,000,000 lb. In January 1919 it was variously estimated as between 1,000,000,000 and 1,800,000,000 lb., the increase being due to the agreed continuance of war production after the Armistice. It was reduced during the spring of that

*Estimated.

The curves based on these figures are given in Fig. 1. The average price of New York electrolytic copper for the pre-war years 1906-1913, inclusive, was 15.274c. Several of the large porphyry mines came into production during this period, otherwise the production and price curves would diverge and show that under pre-war cost-schedules the price of 15.274c. per pound was not sufficiently profitable to stimulate production. The sharp break in production when the price dropped below 14c. in the depression preceding and during the opening months of the War is another indication of this.

In the above table the domestic production is that from United States ores; the imports and exports include ores,

year and in November 1919 was reported as 1,000,000,000 and in January 1920 as 940,000,000 lb. During the first half of 1920 the stock of refined copper was reduced about 150,000,000 lb., but blister probably increased, leaving the surplus in the early summer at about 850,000,000 lb. Exports dropped off sharply during the summer, June actually showing an excess of imports, and the surplus had probably increased considerably up to the time of the break in price to 15c. in October.

The normal consumption of the United States before the War had risen to 65,000,000 lb. per month. It doubled during the War and the indications for 1920 are for about 95,000,000 lb. per month, or 20,000,000 lb. more

than normal expansion would require. This great domestic consumption goes far toward neutralizing the depressing effect of the abrupt shrinkage of the European market.

Copper's war record was unique. The world's production rate increased over 40%, whereas steel increased only about 10%, and coal, pig-iron, and lead never reached their pre-war maximum. See Fig. 2.

Projecting the average curves of the copper industry for the period 1901-1913, inclusive, through to date, they indicate that had there been no war and a constant rate of increase, the United States production for 1920 would have been 1,580,000,000 lb., or 230,000,000 more than the actual, the imports 450,000,000 lb., or 40,000,000 lb. above the actual, the domestic consumption 900,000,000 lb., and the exports would have risen to 1,100,000,000 lb., or 500,000,000 lb. above the actual and within 30,000,000 lb. of the record shipments of 1917.

The excess produced during the past six years over the normal increase was 1,290,000,000 lb. in the United States and about 150,000,000 lb. abroad, the total being equivalent to about one year's United States production.

The monthly statement for copper in the United States for 1920 so far as available is as follows:

Copper in the United States in 1920

	Production	Imports	Exports	Price per pound
Jan. ..	121,903,744	33,224,237	49,680,000	18.918

1,342,998,011* 408,000,000* 580,000,000* 17.522*

*Estimated.

The excess of exports over imports for 1920 is about 178,000,000 lb. For the past three years the total of 350,000,000 lb. shows a drop to one-third the pre-war rate, thus indicating sharply the retrenchment abroad due to unfavorable exchange, money stringency, and the existence of available munition-scrap copper.

Regarding the future of copper, prophecies covering temporary fluctuations are almost worthless, but a study of past performance and consideration of present economic tendencies make some general deductions possible.

It has become too trite to say that the present depression in copper, as in all other basic products, is healthy though disagreeable. Tonics are usually bitter. The reaction has already carried copper far below present costs of production and it is not impossible that we may see 13c. copper before the inevitable adjustment is accomplished.

We produce 60% of the world's copper and ourselves use 35%. The remaining 25% we must market abroad.

The productive capacity of American copper mines was increased 60% and of refineries 70% during the War, but they are this year producing 200,000,000 lb. less than the normal pre-war rate of growth would require. Since the abortive buying of copper by Japan in 1919, how-

FIG. 1. THE COPPER INDUSTRY, 1901-1920

ever, the foreign demand has been light for reasons already given and because Germany, our largest customer, is still almost out of the market.

Until Europe can come back in the market on her pre-war scale, or our production shrinks to the consumption,

FIG. 2. WORLD'S PRODUCTION OF COAL, IRON, STEEL, COPPER, AND LEAD, IN METRIC TONS

the price of copper will be low. Europe will continue to get along on her stock of war scrap until she absolutely must buy or exchange is more favorable. It is conceivable that her scrap will last another six months and that, meanwhile, the copper market will continue in the doldrums. Domestic consumption has been excellent, how-

ever, and there are large prospective requirements. The low price is rapidly curtailing production, the full results of which will not be apparent in the market for several months.

What should be the future price of copper?

A recent tabulation* from the last annual reports of ten of the largest producers representative of all the important copper districts gives their average cost of production at 16½c. per pound. Six of the reported costs were exclusive of depreciation or of Federal tax or other head-office charge, so we can safely assume that these large producers required a selling price of not less than 17.5c. to make a profit, and the rapidly declining production indicates that the smaller producers were not prospering at the prevailing price of 18.69c. None of the important copper dividends declared in 1919 were fully earned.†

Under the conditions prevailing in 1920, it is probable that a price of 20c. would have maintained normal production. Relative costs and returns must ultimately keep step. Deflation is now taking place and the reaction so long delayed will probably have momentum enough to pass the neutral point. The world has not only its regular industrial growth to care for, but unprecedented war-bills to pay, and it will be so difficult to do this on the basis of the pre-war value of money that a 10% advance on the old standards of value seems a moderate depreciation to expect for the world's currency. If this were the only consideration affecting copper, a simple addition of 10% to the pre-war curve of copper prices would tell the story of probable prices; but this is not the only factor.

The copper market was unique during the War, and its future is also unique. The world's copper surplus cannot, with most liberal allowance for war salvage, fill a single year's requirements. A long-postponed era of electrification is due and the productive capacity of the industry, as a result of the War, is already provided. The United States will continue for a long time to be the world's copper store-house, but already depletion is keeping close pace with development, and when the home market absorbs our entire production, the domestic industry will be protected by the freights from South America, Asia, and Africa. This, however, is in the distant future.

A 10% advance on the average price from 1906 to 1913 of 15.274c. makes 16.8c. as a probable average price, with production, export, and consumption as given in the hypothetical figures for 1921. Costs will not apparently average so low in 1921 as 10% over 1913, but it is also certain that exports will not approach the theoretical quantity.

Judging by the analogy of pre-war experience, then, the price of copper for the next decade should fluctuate between 14 and 22.5c., depending upon market conditions; but the average price on which a mine-valuation or other long-time operation should be based may be taken at 17c. The financial optimist who believes in the return

of the old-time dollar, and the industrial pessimist who does not believe in the continued expansion of copper consumption will join hands and continue to figure on 15c. copper.

A Zinc Mine in New York State

The Northern Ore Co., operating the Brown mine, near Edwards, St. Lawrence county, New York, treated 51,411 tons of zinc-bearing ore, which yielded about 10,240,000 lb. of zinc during 1919.

The 400-ft. inclined shaft has been abandoned, and only a vertical shaft 900 ft. deep and an 800-ft. inclined shaft are now operated. Considerable prospecting was done with a diamond-core drill on the large tract of land owned by the company, and the drill was also used in workings to find ore and reduce the amount of drifts run. Ore now being extracted from levels at 840 to 860 ft. is dropped to the 900-ft. level, hoisted, and trammed by means of a gasoline motor to the mill. The mill, which is constructed of steel and tile, is equipped with crusher, rolls, Dorr thickener, and 17 concentrating tables. The ore had been treated by flotation prior to 1919, but that process is not now in use. No jigs are used and the concentrate recovered is exclusively a table product, though experiments that are being made will probably result in an increased quantity of ore being treated and in the installation of jigs to treat middling. The table concentrate, which assays about 32 to 33% of zinc, is treated by 13 Electric Ore Separating Co. machines, which, by removing much of the pyrite, raise the zinc content to 49 to 53%. These electric machines treat wet concentrate, and to avoid the clogging of the riffles in the separator and ensure their proper operation it is necessary to remove by means of a powerful magnet all the small particles of metallic iron abraded from the rolls and crusher.

The average zinc assay of the crude ore treated ranges from 15 to 20%, and the finished concentrate, which is practically free from lead, usually averages about 49%. The pyrite concentrate, which contains about 43% of sulphur, is in good demand when cars are available for its shipment. The developed bodies of ore are large, and it is probable that others will be found on the large tract owned by the Northern Ore Company.

ALMOST every known gem is mined in Australia, but New South Wales leads all other States in the variety and value of precious stones produced. The black opal is said to be Australia's most beautiful gem, and it is claimed that Lightning Ridge, New South Wales, is the only part of the world known to produce it. The black opal has increased in value 300% in the last two years, the best quality bringing from £6 to £8 per carat. The stone ranges in size from 1 to 100 carats. Other stones of commercial importance found in Australia are the pearl, sapphire, diamond, emerald, ruby, topaz, and the turquoise. Of less value but of great beauty and brilliance are the peridot, zircon, tourmaline, and the aquamarine, which are found in New South Wales.

Sundry Details of Sampling at the Garfield Smelter

By Arthur B. Parsons

An accurate determination of the exact amount of metal and other constituents in each lot of ore received at a custom smelter is necessary for two reasons: first, it is the basis of settlement between the smelting company and the shipper of the ore; second, upon the exact knowledge of what is in the ores received depends the intelligent operation of the furnaces. Both these factors are recognized by the American Smelting & Refining Co. as being vital to the success of its smelting enterprises; the company wishes to pay for all the metal in the ore, but it does not want to pay for anything that is not there, and inefficient methods are as liable to be in error on one side as on the other. The first and most difficult step in a determination of the true contents of a shipment of ore is the sampling; this is one of the most carefully organized and thoroughly equipped departments at the Garfield smelter of the American Smelting & Refining Co. In January 1919 there was completed the construction of a new building in which is done the cutting-down of samples of crude ore coming from the sampling-mill together with the final preparation for the assay-office of all samples including ores, concentrates, by-products, and other material to be treated in the smelter. This building was designed after a careful study of the re-

quirements, and included in its equipment are a number of devices that make it of particular interest.

Another notable feature is the Martin unloading and sampling machine recently developed expressly for handling the concentrates, both from tables and from flotation-cells, shipped from the neighboring concentrators of the Utah Copper Co. Since this part of the process precedes the reduction of the samples in the 'bucking plant', as it is called, the Martin machine will be described first.*

The old scheme for sampling shipments of concentrate was the simple, almost primitive, but reliable method of unloading the cars by shoveling onto a belt-conveyor, each fifteenth or twentieth shovelful being set aside on a conveniently placed platform, where it was later half-shoveled once, twice, or even more times, depending upon the number of carloads in the lot.

The belt-conveyors and platforms were placed advantageously so as to expedite the work. The sample so obtained could be depended upon, and, although the amount of manual labor required was considerable, it

*The machine has been patented and the patent has been assigned by Mr. Martin to the American Smelting & Refining Company.

FIG. 1. MARTIN MACHINE FOR UNLOADING AND SAMPLING CONCENTRATE

was not deemed excessive. However, when flotation began to supplant the older methods of concentration a new problem appeared. Instead of the comparatively dry granular concentrates from tables and vanners, a material that was ideal for shoveling, there appeared a product more nearly like soft putty than any other familiar substance. When the Arthur mill was completely equipped with flotation machines and operations were at the maximum, 12 to 15 cars of flotation concentrate were received daily at the smelter. It was hard to get men to work at all and it was still harder to get them to shovel this putty-like concentrate. It had to be chopped to get it on a shovel; and by no means the least difficult operation was to cause it to let go of the shovel when it was once on. The work at one time† was done under contract by Greek and Italian laborers, the prevailing price before the War being 6 to 8 cents per ton, depending upon the moisture content and upon the amount of table-concentrate mixed with the flotation product. It may be noted that at the present time only enough straight table-concentrate is reserved at the plants of the Utah Copper Co. to supply the needs of the sulphuric-acid plant at the smelter. This plant is operated under a joint agreement between the mining and smelting companies, so that it is mutually advantageous to make the separate shipment; although, except for the acid plant, it would be better to mix all the table-concentrate with that from the flotation cells prior to the filtering process. This procedure gives a more porous cake on the vacuum-filters and consequently a drier one. Reverting to the coast of unloading by hand, it may be said that during 1917 and 1918 the contract price increased to such an extent that 20 cents per ton was paid on some lots. Even then strikes caused continual trouble, and congestion of cars in the yards was frequent. Moreover, mixing and half-shoveling were difficult and a great deal of work was needed to get a satisfactory sample.

Accordingly F. M. Martin, chief engineer for the company, with the assistance of his staff, undertook to devise a mechanical process for unloading and sampling the flotation concentrate. Their efforts were successful. After the usual experimenting, altering, and adjusting, a suitable machine was developed. It makes a sample in which both vendor and vendee have entire confidence; it chops up the concentrate and puts it in better condition to be conveyed to the bedding-bins; it is much quicker, and it is more economical.

Inasmuch as the general scheme, besides many of the details, was worked out by Mr. Martin, the machine has been given his name. The first unit, a photograph of which is shown in Fig. 1, was put in operation in the spring of 1919. The illustration shows the mechanism before the housing was built about it. This housing, made of wood, protects the sampling-machinery from rain and snow, and is heated for the convenience of the operator during winter. A second machine has recently

been completed, the only difference being certain changes in the steel frame. A drawing giving the general arrangement is shown in Fig. 2.

The method of operation is as follows: The concentrate is brought in flat-bottomed steel railroad-cars, holding 75 tons, to tracks on either side of the platform on which the unloader operates. The entire machine is mounted on a traveling gantry, which is moved by an electric motor as the car is unloaded; in fact, the gantry-track is so long that a train of five cars can be unloaded without the need for any switching. The actual unloading is done by a 1½-yd. Williams clam-shell bucket so arranged that it can operate in cars on either side of the gantry-track, its load in either event being discharged in a central hopper at the top of the machine. The bucket has square-nosed shells and empties the car almost completely without assistance from hand-shovelers. The receiving hopper has a capacity of about 20 tons; in order to prevent packing too tightly, the force of the fall of the material from the clam-shell is broken by steel I-beams, spaced 3 ft. and resting over the top of the hopper.

The bottom of the hopper, 9 ft. square, consists of a rubber belt supported by, and traveling slowly with, an endless conveyor composed of wooden slats, 2 by 4 in., reinforced on the under side by 4-in. steel channels, these slats being carried on roller-chains. The speed of advance of the belt is variable, depending on the character and condition of the concentrate. It forces a continuous layer of concentrate through a horizontal space about six inches high across the 9-ft. width of the hopper just above the surface of the belt. A belt 9 ft. wide is unusual; the belts so far used were made specially by the B. F. Goodrich company by being placed crosswise in the press. They are six-ply and have a ½-in. pure rubber surface. It was planned at first to have them endless, but as this would necessitate tearing the machine to pieces when replacement was required, the ends of the belt were joined by a square-lapped splice made with copper rivets. The only visible wear after operation for a year is some snagging resulting from scraps of steel or iron that accidentally got into the concentrate.

The essential part of the scheme comes next. It is a 'chopping' device that meets the advancing layer of concentrate as it comes off the belt and cuts it into wide ribbons about ¼ in. thick. The arrangement consists of a central shaft at right-angles to the 'flow' of the concentrate on which are mounted 11 equally spaced discs, 15 in. diam., dividing the shaft into ten 12-in. sections. Threaded through ¼-in. holes in each of these discs, near the circumference are 12 wires that are fastened on one of the end discs and are tightened and kept taut by small ratchets on the outside of the disc at the opposite end. As the cylinder revolves, the wires, of No. 12 spring steel, do most of the cutting, although the discs obviously cut the ribbons into sections. Smaller wire was tried at first, but the continual abrasion wore it out in a few days. No. 12 does better work than larger wire, and lasts from three to six weeks, depending on conditions.

†As described by T. A. Rickard in the 'M. & S. P.' of December 28, 1918. 'The Utah Copper Enterprise, No. IX. The Smelting of the Concentrate'.

Fig. 2. GENERAL DRAWING OF MARTIN MACHINE

Revolving below the falling stream of 'chopped' concentrate with its axis parallel to the disc-shaft is a hollow cylindrical iron drum 30 in. diam. along the entire length of which is a 16-in. opening; that is, a portion of the circumferential surface is cut away. As this drum revolves, a fractional part, a tenth, of the concentrate falls through the opening onto a small 12-in. belt-conveyor traveling in the direction of the axis of the drum, while the remainder falls to the principal 24-in. belt-conveyor, by which the reject, after a series of transfers, is delivered to the bedding-bins. A precaution that has assisted smooth operation is the sanding of the belt-conveyor before the concentrate reaches it. A small portion of a peculiar lime-sand obtained from a deposit near Great Salt Lake is required for fluxing. Accordingly, the storage-bin for this sand is so placed that a quantity flows onto the belt before it passes under the Martin machine. The sticky concentrate falls upon the sand and the difficulty of removing it is lessened. The same belt system was utilized for unloading by hand before the Martin machine was built. To prevent concentrate sticking to the drum, a simple wire scraper is placed near the bottom just over the belt-conveyor. All parts of the machine are designed on the principle that the concentrate must drop vertically onto a moving belt; no matter how steep the incline, a chute will not do, because of the unavoidable accumulation of the extremely sticky material.

The small belt-conveyor within the drum carries a one-tenth cut of the entire bulk of concentrate. At its discharge end is a smaller and simpler wire chopper and a similar drum, which takes a further cut of one in fifteen, this sample being carried on a 10-in. belt-conveyor to an ordinary one-ton mine-car. The car is attached to the housing of the machine and travels in company with it during the unloading of a railroad-car. A new sample-car is used for each 75-ton car of concentrate unloaded. The ma-

chine is operated by direct-current motors at 250 volts. When the Garfield smelter was built, direct current was used exclusively and with a few exceptions it is used today. A 25-hp. motor controls the travel of the gantry, a series-wound 5-hp. motor propels the carriage for moving the bucket crosswise. These are all operated from the crane-man's cab. The sampling machinery is all run through gear and sprocket-chain connections by a variable-speed, 600 to 1800 r.p.m., shunt-wound motor. With flotation concentrate a slower speed is required. To protect the mechanism against breakage in the event of excessive feed, a shearing-pin disc is inserted in the transmission system.

In addition to the flotation product, the Martin machine is used to unload and sample the table-concentrate, which is received in lots of four or five cars, at intervals of two or three days, to supply the acid-plant, as previously mentioned. This material is handled much more rapidly, though quite satisfactorily, and the expense of building a machine would be warranted even if there were no flotation concentrate to treat. Small lots of concentrate from miscellaneous sources are still sampled by the old method, that is, by reserving the fifteenth or twentieth shovelful and subsequently half-shoveling; the point is that the Martin machine is peculiarly adapted for large lots of concentrate of comparatively uniform grade, where no cleaning of the equipment is required when changing from one shipment to the next. The moisture in the flotation concentrate varies between 15 and 25%, the rate of operation of the machine varying with the comparative dryness.

Utah Copper concentrate is being unloaded at the rate of one car, or 75 tons, per hour at a cost of approximately 10c. per ton, including labor, power, supplies, repairs, and depreciation.

The car-samples, weighing approximately half a ton, are cut down to lot-samples of 75 to 100 lb. in a separate room. There are 38 covered bins along two sides of this room, each of which has a capacity of five or six tons of concentrate; these bins are just below the level of the track on which the one-ton sample-cars run, and they open on a lower working-floor entirely covered with $\frac{1}{4}$ -in. steel sheets. The samples from all the cars, from three to six, in a given lot are first shoveled by hand out of the bin; the pile is then moved by half-shoveling, the rejected portion going into wheelbarrows and thence to a small hopper feeding a belt-conveyor which joins that going to the bedding-bins. The sample is then coned and quartered by hand in the usual way by means of a sheet-steel cross until the resultant sample weighs about 100 lb.; it is then put in a covered galvanized-iron can and taken to the bucking-room for treatment, as will be detailed later.

The sampling-mill is a well organized department where the usual precautions are taken in crushing and cutting a sample of from 800 to 2000 lb. of crude ore reduced to quarter-inch. There is nothing particularly novel in the procedure, however, up to the point where this large sample is delivered to the newly built bucking-

plant. This building has a floor-space of 100 by 64 ft. and is built throughout of reinforced concrete, with an exceptionally large window-area, the walls being almost entirely of glass. On the ground-floor are the crusher, rolls, the equipment for mixing and cutting, and storage space for the rejects; on the upper floor are the drying-cabinets, pulverizers, and bucking-boards, the last, as a matter of fact, being used very little, although the whole is known as the bucking department. There are also convenient glass-enclosed rooms for the use of the representatives of the ore-sellers when observing the sampling process.

Samples from the sampling-mill are received in cars on the upper bench, where, after being dampened, if necessary, they are fed by gravity into either of two 12 by 24-in. rolls made by the Mine & Power Machinery Co., the crushed material falling into a specially designed hopper-bottomed sample-buggy. This buggy is made of sheet-iron, is 33 in. square and 35 in. high over all, as shown in the accompanying sketch, Fig. 3. On each side at the top is a hook by means of which the car can be conveniently and quickly engaged by a sling hanging from a one-ton suspended Detroit electric crane, which runs to any part of the room on a series of overhead tracks and turntables. The buggy can likewise be moved about on the floor on four small wheels, two of which are swiveled. The hopper-bottom of the first buggy was made like an inverted pyramid, but it was found that an inverted gable was better for the purpose, and the present buggies or cars are shaped that way. A small arc-gate fitted along the entire vertex of this V-shaped bottom permits the contents of the suspended car to be emptied in a small uniform stream. There are five such buggies in the equipment. The buggy containing a crushed sample is lifted by the crane and carried to a point above a second buggy, fitted with a specially-made 6-mesh screen, fashioned like a shallow funnel. The arc-gate is opened and the ore runs in a sheet-like stream. By whirling the suspended buggy the ore is scattered over the screen and a little manipulation helps the under-size through. The oversize is poured into a wheelbarrow and fed to a Rodgers bell-grinder. This discharges directly into the second buggy, which has been rolled a short distance to be under the spout.

The next step is to mix the sample. Here again two buggies with a large funnel are used, three transfers being usually sufficient to thoroughly mix the 6-mesh material. The operation is thorough, rapid, and economical. After the third mix a one-inch split riffle is attached to the bottom of the suspended buggy by suitable hooks, so that when the gate is next opened only half of the ore goes into the buggy beneath, the remainder being diverted into an iron reject-can. This is repeated until a sample of 75 or 80 lb. is obtained ready for further reduction in the bucking-room upstairs. The exact procedure will depend on the approximate grade of the material being sampled but the variation will be unimportant. The resulting sample is an improvement over that obtained by the former methods of coning and quarter-

FIG. 3. DETAILS OF SAMPLING-BUGGY

ing by hand; being largely mechanical, it avoids many of the vagaries that may result from the personal equation, and at the same time is in accord with the principles on which fair sampling is based; moreover, it is rapid and economical, particularly in respect to the labor required.

An interesting point is the care taken of the rejects pending the final settlement. Instead of the customary wooden box, a clean tightly-covered sheet-iron can is used; there are 100 of these, 36 in. high and 30 in. diam., each mounted on a low wooden stand made of 2-in. plank, and with a clearance between the supports of approximately 4 in. from the floor. The purpose of this stand is to permit the use of a $1\frac{1}{2}$ -ton Stu Bing lift-truck, an ingenious contrivance borrowed from other industries, but well adapted for the work of moving the heavy reject-cans. The operator runs the truck under the stand

and by means of a foot-lever lifts the whole load about an inch off the floor. After moving it to the desired point, the same simple mechanism lowers the stand and can to the floor. Another contrivance is a home-made dumper for reject-cans when they are released by the final settlement on the samples that they contain. It consists of a wood and strip-iron frame into which the can fits, and which is hinged to the edge of a small hopper that feeds a bucket-elevator. This elevator, just outside the building, delivers the reject directly into a railroad-car. The Detroit crane is used to dump the cans into the hopper after they have been suitably harnessed to the frame.

The bucking-room upstairs is divided by means of glass partitions into four sections, each for a definite class of samples. Each has practically the same equipment, the following segregation of the work being made: (1) regu-

FIG. 4. SAMPLING-ROOM AT GARFIELD SMELTER

lar miscellaneous ores; (2) ores rich in silver; (3) ores rich in copper, matte, and other by-products; and (4) Utah Copper Co.'s concentrates. The manipulation of a sample of regular ore will be described. The 75-lb. sample is put through a 12-mesh screen, the oversize being crushed in a Rodgers bell-grinder until the entire sample has passed the screen. This crusher can successfully grind material that is somewhat damp. Instead of a cloth, a 16-in. cubical box of galvanized iron with a small door or gate at one corner is used as a mixer. This cube is placed in a lathe-like machine that revolves it at about 20 r.p.m., two opposite corners forming the axis of revolution. After mixing for from two to five minutes the sample is cut to a bulk of approximately 60 oz. by means of a $\frac{5}{8}$ -in. Jones riffle, and is then dried. Each section is equipped with a drying-cabinet composed of a series of shelves made of steam-pipes, and fitted with 12 separate doors. A Bristol recording thermometer is attached to each drier, the line of standard temperature, 230°F., being closely followed at all times. The dried sample is then ground in a McCool pulverizer, a disc machine with an accentric motion; any oversize on a 120-mesh screen is either run through the pulverizer a second time or is ground by hand on an ordinary bucking-board. The final mixing is done in a small 8-in. revolving cube similar to the one previously mentioned. When revolved at slow speed this mixer does remarkably good work, one point in its favor being the absence of a tendency to classification, which is frequently found when mixing is done improperly on a cloth. An advantage is that the mixing is uniformly good, providing the cube is kept revolving for the specified time; the result is not affected by carelessness or inexperience on the part of the man doing the work. After mixing, the sample is divided into the required number of portions for analysis by the vendor of the ore and by the smelting company, for umpires, and for extras.

I am indebted to A. H. Richards, general superintendent of the Garfield smelter, for his kindness in authorizing the publication of these notes, and to N. L. Stewart, chief engineer at the plant, for courteous assistance in supplying me with detailed information.

The Broken Hill Strike

The Broken Hill strike, said to be the longest in history, has at length come to an end. When the last mail left New South Wales, about the middle of November, work had been resumed at one mine, but it was expected to be several weeks before operations could be got into full swing at all of the mines. Since the special tribunal appointed to settle the dispute gave its decision a couple of months ago, several conferences and controversies have taken place between the men and the companies as to just what the decision meant and on other matters, but an understanding, at least for the time being, had been arrived at, and the mines were ready for active work as soon as circumstances permitted. There are questions still outstanding, but both sides have been

so 'filled up' with this strike, which has lasted between 17 and 18 months and is estimated to have cost the nation about £12,000,000, that there is not expected to be any more striking for a long time. Another thing that makes this less likely is that the stringency of the money market throughout Australia is beginning to cause unemployment, and the time is believed to be approaching when all workmen will think more seriously than they have done in the past before throwing up regular and well-paid occupation.

Will This Work?

The question as to what shall be done with our dumps has long been a subject of discussion in mining and other circles, says 'The South African M. & E. J.' The low gold content of the residues, especially of recent years, due to improved metallurgical processes, has made the question of re-treatment of the dumps a remote possibility only. In any case the re-treatment of sorted residues containing one pennyweight or less has not hitherto been attempted on the Rand. A brief description of a novel plan is here given in order that our readers may understand the nature of the process and be enabled to form their own opinions as to its value. Seemingly it is based on Rittinger's law of concentration of particles of differing specific gravity in water. The sand is acted upon by water under a pressure of 35 lb. per square inch, and is thereby thrown into the atmosphere; in its descent the particles of different low gravity become separated and fall in layers. The heavier concentrate, which contains most of the gold, is collected and passed over Wilfley tables for final concentration, after which the recovered concentrate will be ground fine in tube-mills, or treated direct with cyanide to extract the gold; the other portion of the concentrate will be roasted for the ultimate recovery and the manufacture of sulphuric acid. A unit of three machines will treat about 1200 tons of sand per day, the concentrate from which will give from 12 to 25 tons per day for Wilfley-table treatment. Should the sand be refractory, roasting of the concentrate may be done, or fine grinding, which will have nearly the same effect so far as regards the extraction of the gold. The residue remaining after the treatment for the recovery of the gold will be further treated for the extraction of sulphuric acid, and with the very large tonnage to be treated daily this will form a considerable source of revenue, as the acid is in demand for many purposes on the Rand and elsewhere, as, for instance, in reduction works and in explosive-factories. The sand, it is claimed, will, by the process, be completely purged of its cyanide, and will then be amenable to treatment for the manufacture of bricks, concrete, etc., thereby affording a third useful industry. The pyrite residue can also be sold at a profit. Of the claims advanced we shall soon have demonstrable proof, since a new company is about to start treating at least one large dump near Johannesburg, and has on hand contracts for the treatment of millions of tons of residue.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

RICH ORE FOUND AT OATMAN.

CLIFTON.—Final payment to the Stargo Silver Belt Mining Co. on 26 claims was made on December 16 by the Stargo Mines, Inc. It is announced by George J. Stoneman, president of the company, that the erection of the 50-ton cyanide plant will be delayed and that \$50,000 will be spent immediately in developing the lower levels of the mine. It is hoped that the development will justify the erection of a 100-ton plant the latter part of 1921. Milling tests on the ore have been made by the General Engineering Co. of Salt Lake City and the plans for the mill are complete. The Stargo Mines, Inc., has shipped high-grade silver-gold ore continuously for 15 months to the smelter at Douglas. The stockholders of the company are residents of Arizona.

The Sierra De Oro Mining Co. has been sold at Sheriffs sale to D. M. Potter for \$22,338 and costs. This property consists of 17 patented claims and a large acreage of patented and unpatented land on the San Francisco river, including water-rights and placer deposits, and adjoins the Copper King property of the Phelps Dodge Corporation. The development consists of a 2000-ft. tunnel which if continued should cut the vein system at a depth of approximately 1000 ft. below the outcrop.

JEROME.—The Jerome Superior Copper Co. has been closed down since December 13 and the shaft allowed to fill with water to the 700-ft. level. A legal fight for control of the company has been launched by a group of Los Angeles stockholders who filed complaints with the Arizona Corporation Commission charging George Mitchell, manager, and M. P. Frasier, president, with mismanagement. The Commission in its filing upon the case has urged the stockholders to settle their difficulties and called attention to a provision of the civil code charging the Commission to communicate with the attorney-general to apply to the courts for the appointment of a receiver where it appears that the business of an investment company is being conducted in an unsafe and unauthorized manner.

KINGMAN.—Drifting toward the ore-shoot on the 350-ft. level of the I.X.L. mine is now under way, the station and sump having been completed a few days ago. The ore opened on the upper levels has been sufficiently plentiful to warrant confidence in continuation at depth. The I.X.L. vein is reported as being the largest in the district, being 40 ft. wide in some places. Very rich ore is reported as having been opened in a winze on the 185-ft.

level of the Golden Star mine at Mineral Park. A recent shipment of ore to the Humboldt smelter yielded satisfactory returns and shipments will be continued. A large tonnage of good mill-ore is reported as having been opened.

MIAMI.—Full operations at the Van Dyke Copper Co. are now to be resumed as a result of the increased power recently made available by the local power plant. During the past two months only sufficient power to keep the mine open has been at hand. Lateral exploration is to be continued at two horizons; at the 1220-ft. level where the station and ore-pocket have been cut and 150 ft. of drifting has been done; and at the 1550-ft. level where only 50 ft. of drifting has been done. All this work has been done in the two ore-horizons indicated by the shaft and diamond-drill work. The upper ore-zone is copper carbonate and the lower is disseminated chalcocite. It is the policy of the company to push development work at both levels.

OATMAN.—Since the connection by the United American with the Tom Reed drift on the Aztec vein a station is being cut in the ore-shoot preparatory to sinking a winze to prove the depth of the ore recently opened. It is reported that this orebody is 300 ft. long and 30 in. wide and will average about \$100 per ton in gold.

PRESCOTT.—The Howard Copper Co. has acquired a two-thirds interest in the Olive, South Extension of R & H, and Alice claims from J. J. Fagan of Phoenix, trustee for the owners, for \$70,000. The claims are situated in the Black Canyon district. While undeveloped the claims are said to be promising prospects.

SUPERIOR.—It is reported that as a result of the recent visit of Messrs. Stephen, McKay, Smith, and Defty, the promoters of the Queen Creek Copper Co., new and more powerful machinery for development work is to be installed. Arrangements for power have been made with the Superior Light & Power Co. The ore of the Queen Creek mine carries gold and copper, and development, which has been under way for several years, is reported to have opened a considerable quantity of ore.

MICHIGAN

CALUMET & HECLA.—COPPER RANGE.—QUINCY.

HOUGHTON.—November production figures for the Calumet & Hecla group of mines shows a decrease of 616,739 lb. from the October total. While the curtailment program became effective November 16, several

weeks elapsed before the new schedule became fully operative and the results will not be noted until the December figures are announced. November production was 7,326,763 lb. of refined copper. It is estimated that a decrease of at least 1,000,000 lb. will be revealed by the December figures, due to the closing of Osceola, Allouez, LaSalle, and White Pine.

Copper Range will close the year with finances and copper on hand about the same as at the end of 1919. It is expected that production for December will show a slight increase due to additional men employed at all three mines, Champion, Baltic, and Trimountain. The yield from these mines shows no material change from month to month and the average for the year will be about on a par with that of last year. Champion rock averages about 36 lb. of refined copper per ton, Baltic about 33, and Trimountain 24. Costs are estimated about 15c. per pound and at the present price of copper the property cannot do much more than break even. Normally, Copper Range should produce copper at about 10c. per pound. The company has no fixed policy in regard to 'openings', but keeps well ahead of immediate requirements. During the period of curtailment, openings will be vigorously extended and the property placed in the best physical condition to meet increased production when the market strengthens. Copper Range finds that its mechanical devices are operating satisfactorily and it is expected they will make a material difference in costs, at the same time making possible a greater output. The introduction of mechanical scrapers and shovels, in fact, is the biggest accomplishment of the year in the Lake district.

Repairs have been completed in No. 4 shaft, Wolverine, and the mine is again 'hitting its stride' in production. Output for the past week has been averaging 900 tons per day. No. 4 shaft was out of use for several weeks to permit the replacing of concrete supports by timber between the 30th and 32nd levels. The shaft-pillars in this part of the property are being removed from the 38th level upward, and the yield per ton in refined copper is holding near 17 lb. The removal of arches and backs of stopes, and the widening out of drifts to both walls of the vein, continue. The showing in No. 3 shaft is favorable and the result will be a material increase in copper output this month. 'Rock' shipments now are sufficient to keep two heads in the Wolverine mill in continual operation.

In its No. 2 shaft, Quincy is penetrating territory, south and under the shaft, acquired from the Hancock Consolidated in 1915. The lode is uniformly mineralized and rich in mass and barrel copper. The new shaft recently put in operation at No. 2, with a hoisting capacity of 13,500 ft., will materially aid in the deeper development of this shaft and lengthen its life a great many years. Production of the mine is now on a 60% basis and there will be no further curtailment. Production for the year will show a considerable falling off from that of 1919. During the early months of the year the property was affected by a shortage of labor, a con-

dition which prevailed throughout the district, and of late months the low metal market has contributed to a lessened output. Last year Quincy produced 19,476,770 lb. of refined copper, over 2,000,000 lb. less than normal. Quincy, however, is in a position to readily take advantage of an advance in the price of copper. It has openings in excess of 100 miles in ground that will average 17 lb. of refined copper per ton, and in at least two shafts, No. 2 and 8, the 'rock' is increasing in copper content. Improvements in hoisting-equipment, underground electric haulage, new re-grinding machinery, increased capacity of stamp-heads, reduction of loss in tailing, and extensive changes in the smelting-plant will enable the management to quickly increase production when needed and contribute to a lessening of costs.

NEVADA

MILLING PLANT PLANNED FOR THE EUREKA CROESUS.

EUREKA.—The Eureka Croesus produced to June 1 of this year from new workings, 4814 tons of ore of a gross value of \$311,806, or \$64.47 per ton, according to a report to stockholders written in September and made public now. The metallic content per ton was 0.68 oz. gold, 24 oz. silver, and 16% lead. Freight and treatment charges totaled \$10 to \$19 per ton. The cost of mining was \$93,904 and the operating expense \$85,194. "The greatly increased cost of labor, freight, machinery, supplies, and material of every kind makes necessary the erection at the mine of a plant for treating medium and low-grade ore," says the report. A method has been perfected for treating this ore, "of which we have enough to keep a plant in operation for years". The directors have authorized the sale of \$1,500,000 worth of additional treasury stock to finance the plant.

MANHATTAN.—The report of W. L. Taylor, general superintendent of the White Caps, covering operations from May 13 to December 9, shows that 1955 ft. of development work was done during the period. Mr. Taylor says that work on and between the 600 and 800-ft. levels in the east orebody "indicates a probable tonnage of 15,000 to 20,000 tons of ore of an average value of about \$18 per ton". A cross-cut to a faulted segment of the White Caps limestone on the 550-ft. level has exposed ore 41 ft. long, 12 ft. wide, and assaying \$22.90. The report says work is being done in this territory in a search for other orebodies and that, when this has been completed, work will be done to explore these bodies on the 310 and 800-ft. levels, which are 700 ft. apart on the dip of the vein. When this orebody has been opened on the 800 and 310-ft. levels the company should be able to resume milling at a profit, according to the report. It is expected to complete the work by June 1 of next year. The largest business houses in Manhattan were burned recently with a loss estimated at \$30,000. The mines were not damaged.

DIVIDE.—A meeting of stockholders in the East Divide has been called for January 15 to consider increasing the capital stock from 1,500,000 to 2,000,000 shares, the ad-

ditional stock to be sold and the funds to be used for further work. The company, from the bottom of a 400-ft. shaft, has done 1400 ft. of lateral work since October 1918. The main cross-cut, driven east, is 645 ft. long, with north and south drifts at the 480-ft. point. The south drift, on the foot-wall of a vein 45 ft. wide, has been driven 245 ft. Important results have not been obtained, but general conditions are regarded as justifying much further work. The south drift is to be continued, the vein in which it is driven to be prospected at a depth of 200 ft., and sinking of the shaft may be resumed.

CUPRITE.—The Foster Mines Co. has leased for 50 years 300 acres containing a silica deposit and, starting

treinely fine dust will settle. The tube and tower will contain boxes into which the various grades will settle, the finest being farthest from the blower. The Hardinge mill will be used to grind the coarser air-floated material in the tube so as to produce quickly the finer grades when there is a demand for them exceeding the production direct from the crusher product. Various grades of silica are used in many industries and the latest use for it is in the manufacture of 'woodstone', made by mixing wood pulp, silica, and cement. This is used in making sinks and similar articles. Silica also is used in making brick, for abrading purposes, as a wood filler, in the manufacture of porcelain, paints, scouring-soap, and in making art-glass, pottery, fused-silica ware, and as an

COAL MINES OF THE UTAH FUEL CO. AT CASTLE GATE, UTAH

on a small scale, Ernest D. Foster, manager, says he hopes eventually to ship 5000 tons of refined silica monthly. Belgian silica-sand of a grade that is used in the manufacture of glass is being laid down at San Pedro, California, for \$6.50 per ton, according to Foster, who says he does not expect to be able to compete with this until he can assure the railroads enough business to justify a lower freight-rate, but he does expect to be able to make a profit of \$5 to \$7 per ton on air-floated silica such as is used in the manufacture of paint. The deposit, 2½ miles from the railroad, is pure white, soft, breaks easily, with 25% going into 300 to 400-mesh material. He plans to erect a plant consisting of a crusher, wire-cloth screens, an 'air-flotation' machine, and a Hardinge conical 6-ft. silice-lined pebble-mill. The flotation machine, specially designed, will consist of a conical tube set horizontally, into which the fine silica will be blown from the smaller aperture after being crushed and screened, and a 30 or 40-ft. tower in which the ex-

insulator of electricity, for which it is far superior to glass.

UTAH

GENERAL SURVEY OF MINE PRODUCTION DURING 1920.

SALT LAKE CITY.—During 1920, the metal-mining companies of Utah paid the following dividends:

Cardiff Mining Co., Big Cottonwood.....	\$ 75,000
Chief Con. Mining Co., Eureka.....	353,692
Daly Mining Co., Park City.....	45,000
Daly West Mining Co., Park City.....	225,000
Dragon Con. Mining Co., Eureka.....	37,500
Eagle & Blue Bell Co., Eureka.....	311,605
Grand Central Mining Co., Eureka.....	42,000
Iron Blossom Mining Co., Eureka.....	50,000
Judge Mining & Smelting Co., Park City.....	180,000
Tintic Standard Mining Co., Eureka.....	469,880
Utah Apex Mining Co., Bingham.....	150,000
Utah Copper Co., Bingham.....	9,746,940

Total\$11,686,617

The mineral output of Utah during the past year was about the same as for 1919, in spite of a constantly declining market price for lead and copper. According to preliminary figures, the gold output of the State during 1920 was 89,750 oz., as compared with 104,464 oz. for the previous year. The output of silver is estimated at 11,839,621 oz., as against 11,649,961 oz. Had it not been for the Pittman Act, which stabilized the price of silver at \$1 per ounce, this figure for 1920 would have been considerably less. The copper production for 1920 is estimated at 115,000,000 lb., as compared with 124,061,087 lb. for 1919. Practically all of the copper produced in Utah during the past year came from the Utah Copper mine at Bingham; the output of this property being estimated at 5,800,000 tons, with a gross production of 106,500,000 lb. The lead output during 1920 is estimated at 146,002,000 lb., as compared with 123,829,051 lb. for 1919. The production of recoverable zinc will probably be about the same as for 1919, or about 4,500,000 lb. The four smelters in the State were in operation throughout the year, on a reduced basis. High prices for silver and lead during the early part of the year stimulated the mining of those metals, but with the outlaw switchmen's strike in April and May, the smelters were unable to handle consignments, with the result that embargoes were placed on most of the large producers. This unfortunate condition existed for some time, with the result that operations were necessarily curtailed at the mines at a time when the metal markets were favorable to the operators. During the last six months of the year, with constantly declining prices for silver, lead, and copper, production began to fall off in every district in the State; and when freight-rates were increased on August 26, the smelters immediately increased their rates, which added a further hardship on the small producers. During the latter part of October, the Public Utilities Commission compelled all of the mining companies holding special contracts for power-service with the Utah Power & Light Co. to accept such service on schedule rates, which were from 50 to 100% higher than contract rates. As a result of this decision, the Judge electrolytic smelter at Park City, the only plant of its kind in the State, suspended operations. The new zinc-oxide plant at Murray will be ready for operation early in the new year, which will undoubtedly stimulate the mining of zinc ores in this State since the Grasselli Chemical Co. withdrew from the local field some months ago. At the close of the year, production of all the important metals is about at its lowest ebb, but as most of the large producers of lead and copper have been doing considerable development work during the past 12 months, their properties are in a position to increase output easily as soon as metal-market conditions justify.

A meeting of operators of lead mines in Utah was held at the office of the Utah Chapter of the American Mining Congress on December 21. A resolution was adopted, urging Congress to pass a higher protective tariff on lead. The present tariff is three-quarters cent per pound. Owing to the large stocks of the metal in

Europe, which was purchased from this country during the War, and attracted by the price of eight cents per pound some months ago, this metal started coming back to the United States. With lead at five cents per pound, even the largest producers in this State are having a hard time to make both ends meet, and the Utah Apex property at Bingham, the largest producer of the metal in the State, has closed down. The committee appointed to present the resolution to Congress was comprised of Ernest Bamberger, W. Mont Ferry, Fred Cowans, E. J. Raddatz, Imer Pett, and G. W. Lambourne.

EUREKA.—With the payment of its dividend on December 23, the stockholders of the Tintic Standard Min-

MAP OF BRITISH COLUMBIA

ing Co. received a brief report, covering operations during the third quarter of the year. During that period there was shipped 31,090 tons, with a gross value of \$1,353,421, and after deducting freight and smelter charges, the net return was \$697,305. There was opened on the 1100-ft. level a large stope of ore, as well as one on the 1250-ft. level, while stope No. 5 on the 1200-ft. level is increasing in size and the ore in value. During the week ending December 18, the company shipped 69 cars of ore, approximately 3100 tons. This is the largest weekly output of ore from any one mine in the history of this district, the nearest approach having been 66 cars shipped by the Chief Consolidated in the early part of 1920. The Tintic Standard now has 275 men in its mine, the largest number in its career, while 125 men are engaged in the construction of the new milling plant at Warm Creek. The process to be used is identical with that in successful operation in the chloridizing-roasting plant of the Tintic Milling Company.

BRITISH COLUMBIA

TRAFFIC ON THE DOLLY VARDEN RAILWAY SUSPENDED.—

TIDEWATER COPPER CO. MAKES FIRST SHIPMENT.

PRINCE RUPERT.—Heavy snowstorms closed the Dolly Varden-Alice Arm railway on December 16. About 27,000 tons of ore containing more than a million ounces of silver has been shipped from the mine. Though shipping has been stopped until next May, mining and development operations will be continued, and between 70 and 100 men will be employed. There was between three and four thousand tons of ore ready for shipment when the railway closed, and, as this quantity will be greatly increased during the winter, it is expected that the output of the mine next year will be nearly double that of the past year. The railway has been greatly improved during the past season, and its capacity has been practically doubled. The new hydro-electric plant was put into operation last week. This plant will supply both the Dolly Varden and the Wolf mines with power. The first unit has a capacity of 500 kw.; other units will

peared on the list for the first time this year with a shipment of 19 tons. The Josie mine, at Rossland, perhaps better known as Le Roi No. 2, closed down for an indefinite period on December 4. During the present year the mine has shipped nearly 12,000 tons of ore to Trail, and its closing cuts off practically the last supply of copper ore, except that received from the company's own Rossland mines, so the probabilities are that when the present supply of ore is smelted the copper department at the smelter will close.

GREENWOOD.—The Providence mine, which has been shipping on an average about 40 tons of high-grade ore per week to Trail, has been closed temporarily. A compressor has been purchased, and when this is in place it is thought that it will reduce the cost of mining sufficiently to justify re-opening the mine. The ore is rich in silver, and the slump in the price of that metal is the reason for closing the property.

ANYOX.—By a vote of 750 to 175 the employees of the Granby Consolidated Mining, Smelting & Power Co. decided to accept the new wage-rate offered by the com-

HIDDEN CREEK MINES OF THE GRANBY CONSOLIDATED CO., NEAR ANYOX, B. C.

be added as increased power is needed. Water-rights capable of developing 8000 hp. have been secured, and other mines in the district will be supplied with power. The Granby Consolidated M. S. & P. Co. has made a reduction of 75c. per day in its wage-scale. When working at capacity the company gives employment to more than 1000 men.

VANCOUVER.—The provincial branch of the Canadian Institute of Mining and Metallurgy will hold its spring meeting in this city on February 9, 10, and 11. H. Mortimer Lamb is chairman of the executive committee, which includes G. C. Mackenzie and R. W. Brock. A number of papers have been promised.

TRAIL.—The Consolidated M. & S. Co. continues to maintain the rate of output from its mines. Out of a total of 9093 tons of ore received at the smelter during the second week in December, 8126 tons came from the company's mines. The other important producers were: Bluebell, Riondel, 220 tons; Josie, Rossland, 285; and North Star, Kimberley, 165. Society Girl, Moyie, ap-

pany. H. S. Munroe told the men definitely when the proposal was put to them that the company could not carry on business under existing conditions at the present price of copper, and that in the event of their refusing to accept the reduction the plant would be closed. The new rate, which is a reduction of approximately 75c. per day, went into effect on January 1, and is to prevail for the first three months of the year, at the end of which the matter will be taken up again.

VICTORIA.—The Tidewater Copper Co., which is operating a property at Sidney Inlet, on the west coast of Vancouver Island, has made its first consignment of concentrate to the Tacoma smelter. The shipment comprises 400 tons and is valued at between \$20,000 and \$25,000. The Tidewater company has been operating for the last three years, and is said to have spent \$650,000 in development and plant. A considerable tonnage of ore has been demonstrated, which, it is stated, is sufficient to keep the plant operating at its present capacity for ten years. The ore contains about 2% cop-

per, and some gold and silver, the concentrate running \$3 to \$4 in gold and 5 to 7 oz. in silver. The whole plant is operated by water-power, and consequently can be run cheaply. It is stated that it can produce copper profitably at present price of the metal. About 125 men are employed.

ONTARIO

PRODUCTION AT COBALT CURTAILED FURTHER.

COBALT.—Operations have been narrowed down at least 25% in the Cobalt district. The only complete shut-down among the producers is the Temiskaming mine. This week, the Kerr Lake will discontinue production, but will carry on development work during the winter. The Dominion Reduction custom plant will curtail operations until spring, this plant having operated on ore coming chiefly from the Kerr Lake mine. Work has been started on the Haileybury Frontier property in South Lorrain, where an effort will be made to mine the deposits of cobalt which are found in comparatively wide veins. The property lies in the vicinity of the Keeley Silver mines, and the operators believe the cost of work will be offset to some extent by the recovery of some silver as a by-product. This is the first effort made to mine cobalt in this district other than as a by-product of the silver ores.

A winze at the 385-ft. level of the Chambers-Ferland mine has been sunk through the layer of slate in which the cross-cut lies and is expected to reach the underlying conglomerate formation this week. Veinlets found extending up into the slate and which contain some silver, are believed to have had their origin in a silver deposit in the conglomerate. Arrangements are being made to make a bond issue of \$35,000 on the Hudson Bay mines, the bonds to be supported by a mortgage on the property. The money is intended to finance operations until such time as shipments are resumed in the spring. Announcement is made that ore sufficient to warrant this plan is in sight. The shareholders will be asked to ratify the scheme this week. Heavy bullion shipments are being made from the Nipissing mine, a total of 561,216 oz. having been shipped during the first three weeks of December. The greater part of the metal has been consigned to Shanghai.

Preliminary estimates of the output of the silver and gold mines of Northern Ontario show a total of approximately \$23,295,088. The amount of gold produced exceeded the silver output, but the figures dealing with by-products appear to indicate a fair margin of total value in favor of the silver mines. Following is a summary:

Silver Mines

Silver (9,931,143 oz.)	\$9,905,088
*By-products	1,800,000
Total	\$11,705,088

*The heavy demand and high quotations for cobalt was the reason for the high value of by-products from the silver mines.

Gold Mines

Gold	\$11,500,000
By-products	90,000
Total	\$11,590,000
Total gold and silver	23,295,088

The silver mines of Cobalt and district have produced a total of \$191,704,275 since 1903. The gold mines, made up chiefly of those at Porcupine and Kirkland Lake, have produced \$59,879,262 since 1910. The combined total amounts to \$251,583,537.

Dividends Paid

	1920	Total to date
Silver mines	\$3,458,142	\$81,975,040
Gold mines	3,240,042	18,785,280
Total	\$6,698,184	\$100,760,320

BOSTON CREEK.—A discovery of almost pure chalcopyrite has been made in the west cross-cut at the 500-ft. level of the main shaft of the Miller Independence. The mineral occurs in the form of a small solid vein paralleling a calcite vein. Assays in bulk show 32.48% copper together with \$2.80 gold and 1.3 oz. of silver per ton. A copper-bearing vein, showing on the surface, which has been traced for a considerable distance, has yielded assays of only 3 and 4%, but the new find indicates that copper deposition increases with depth.

PORCUPINE.—The report of the Porcupine Keora for the year ending December 1 states that No. 1 vein, 40 ft. wide on the surface, has been explored by diamond-drilling to the depth of 1000 ft. and gold content shown to be \$6 per ton. The manager reported, as the result of further drilling, the discovery of No. 5 vein with a width of 20 ft. and an average value of \$110 per ton, and No. 6 vein, having a width of 10 ft. with an average of \$46.50 per ton. Arrangements were made to sink a shaft to 250 ft. and run a cross-cut to open these veins. Three 40-acre lots adjoining the company's property to the north had been purchased, bringing up its total holdings to 200 acres. Development work is proceeding steadily.

MANITOBA

RAILROAD TO FLIN FLON PROJECTED.

THE PAS.—The Provincial government has announced, through Edward Brown, Provincial Treasurer, that, provided the Flin Flon syndicate will deposit one million dollars with the Government as an assurance that a smelter will be erected, and tonnage to pay a railroad supplied, the road now being surveyed from The Pas to the mine, will be built at the expense of the Province. It is understood that these terms will be accepted by the Flin Flon syndicate. The Federal government will, so Mr. Brown says, remit all taxes on copper for ten years, and not five as reported. This will be a very large undertaking. There are more than 20,000 tons of ore proved by shafts, drifts, and drill-holes, and the average value is supposed to be almost \$10 per ton. If the railroad is built it will be operated by the Canadian National Railways, that is to say, be part of the Federal railway system.

CALIFORNIA

Nevada County.—Despite the adverse conditions, increased clean-ups are reported in most of the producing gold mines of the district and the output is increasing each month. At the Empire, the operations are the largest in the history of that property and the North Star is also increasing its activities. The management of the latter mine has announced, however, that several months would be devoted to development and other dead work before any particular effort at large production was made. The producing mines here now include the Empire, North Star, Idaho, Maryland, Sultana, Alcalde, Grass Valley Boundary, and various small properties.—M. H. Brock, manager for the Grass Valley Boundary Mines Co., the newest company in the Grass Valley district, announces that the first clean-up at the mill has just been made and that the returns show approximately \$8.50 per ton. The milling was entirely on the dump, which was accumulated while the shaft was being sunk and drifts run, and is stated to contain a large amount of waste rock.

IDAHO

Coeur d'Alene.—Five thousand dollars for a 30-day option on 1,010,000 of the 2,000,000 shares of the capital stock of the Black Bear Mines Co. has been paid. The option has been filed with the county recorder by Robert McLaughlin. It was signed by Dennis Goggin and R. E. Weniger, two of the directors, and by J. L. Fitzgerald, secretary. If McLaughlin exercises the option he must pay 25c. per share for the stock. This places the value of the property at \$500,000. He agrees to pay on the purchase \$10,000 in the first six months and to start work in 60 days and do not less than \$5000 worth of work per month.—Wages of miners and muckers in the district were reduced \$1 per day on January 1. The 'going' wage beginning the first of the year will be \$4.75 per day. It was said that there will be little activity in the mines until spring. The only exception to the \$1 per day reduction is the Bunker Hill & Sullivan mine, which now pays \$5.25 per day, and will reduce its scale 50c., making the new wage \$4.75.—Additional men have been put to work by the Midnight Mining Co. to push the raise which is now up 400 ft. and has 700 ft. more to go.

MONTANA

Butte.—A general wage reduction throughout the Butte district will go into effect on January 20, those now receiving \$5.75 or over will be cut \$1, those now receiving under \$5.75 will be cut 75c. Single men are being laid off at nearly all of the mines.—The Butte-Plutus mine, which recently closed down owing to the inability to handle the additional water, has installed a new electric pump. It is understood that a contract has been let for the sinking of the shaft 50 ft., to the 400-ft. level, and driving a cross-cut to the New Mapleton, a distance of about 1500 ft.—Oscar Rohn, manager for the East Butte Co., states that unless the financial situation becomes so serious that the company cannot sell copper, or cannot borrow any money on the copper it is producing, there will not be any shut-down. If the East Butte should shut-down the Davis-Daly would necessarily follow, as the ore from its Colorado mine is treated at the East Butte smelter.

Helena.—Mining activity in this district is at a low ebb. The low price of lead has had a depressing effect generally. The concentrating plant of the New York-Montana Testing & Engineering Co. has closed until metal prices shall be better, and the East Helena plant of the American Smelting & Refining Co. has laid-off many men, and reduced wages for the same reason. Many of the mining men of Helena are now turning their attention to the new oil-fields in Fergus county. The Cat Creek field looks particularly promising, there being now ten producing wells in this field, with a combined flow of about 12,000 bbl. per day. The oil had a high gasoline content. Many wells are being drilled, and a great deal of activity is looked for in the spring. The oil-sands are penetrated at about 1600 ft. depth.—The Liverpool mine in Lump gulch is maintaining regular shipments of silver ore to the East Helena smelter. About 30 men are employed. The mine has a 750-ft. shaft. The rich silver ore in the upper levels was worked out years ago, and the ore at present is being taken from stopes from the bottom level. The present operators have re-timbered the shaft, and installed electrical equipment, power being furnished by the Montana Power Co. The company plans to sink in the near future. Carl J. Trauerman is manager. Other Lump Gulch mines which are operating are the Little Nell, Free Coinage, and Mammoth. These properties are developing. There is some activity in the Nigger Mountain region, south of Elliston. The Charter Oak has a shipment nearly ready and the Big Dick and the Julia are developing. The Monarch mine on Bison mountain is closed for lack of funds to complete the development work. The property is well equipped with steam-driven compressor, drills, saw-mill, bunk-houses, and boarding-house.

Neihart.—The old Barker or Wright & Reynolds mine is producing some rich silver-lead ore, according to reports. The ore is being shipped to the railway by motor-trucks. T. C. Power, of Helena, owner of the property, is reported to have recently refused an offer of \$1,000,000 for the mine.

PERU

Cerro de Pasco.—The net income for the Cerro de Pasco Copper Co. for 1920 will be approximately \$4,000,000. This does not include undistributed profits of subsidiary companies, which have averaged approximately \$1,000,000 annually for four years ended December 31, 1919. Notwithstanding increased production during the war period, ore-reserves are considerably larger than when the company was organized. In addition to copper ore-reserves, engineers estimate a large deposit of oxidized silver and pyritic silver ore, assaying from 8 to 18 oz. per ton. Preliminary reports estimate the available quantity of this ore in excess of 100,000,000 tons. Of this, about 18,800,000 tons are definitely reported and contents calculated at over 200,000,000 oz. of silver.

In 13 years ending December 31, with 1920 partly estimated, the company has produced 660,799,611 lb. of copper, 45,904,700 oz. of silver, and 292,825 oz. of gold. Silver production in ounces for the last five years, with 1920 estimated, has been as follows: 1916, 4,209,659; 1917, 5,556,735; 1918, 5,051,900; 1919, 5,325,320; 1920, 5,595,084.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. W. Draper is here.

J. M. Campbell has gone to Rangoon, Burma.

J. R. Finlay is now residing at Redlands, California.

Millard K. Shaler is returning from the Congo to Brussels.

J. F. Grugan is on his way from New York to the Transvaal, in South Africa.

Albert Roberts has returned to San Francisco from a visit to the South-West.

V. Harper Carter, a mining engineer from Platteville, Wisconsin, is at Oakland.

Walter Fitch Jr., of Eureka, Utah, is spending the holidays in southern California.

C. E. Mills, head of the Apache Powder Co., has been visiting the Bisbee district, Arizona.

W. E. Thorne has returned to Santa Cruz, California, from Nigeria. He expects to return thither in April.

Julien Raick, a graduate of the university of Liège, is taking a post-graduate course in mining at Stanford university.

S. M. Parker was in San Francisco last week on his way from Corinto, Nicaragua, to Morgan Hill, California, where he will reside.

Frank E. Grant, superintendent of steam-shovel mines for the Nevada Consolidated Copper Co., is here from Ruth, Nevada.

Victor C. Alderson, president of the Colorado School of Mines, passed through San Francisco last week on his way to Los Angeles.

Hervey Gulick left India in the middle of November, and will reach San Francisco in February, after having visited Manila and Honolulu.

H. H. Claudet has taken over the Ottawa branch of the General Engineering Company and will conduct that office and laboratory on his own account.

Gelasio Caetani was elected a Councilman at the head of the poll of Rome, but he did not see his way to accept the mayoralty, for which he had been nominated.

Clinton W. Bagwill, for the past 10 years chief clerk at the mill and smelter of the Nevada Consolidated Copper Co., at McGill, Nevada, has resigned. On January 1 he became associated with the Granby Consolidated company in British Columbia.

John M. Hayes, whose resignation as treasurer of the Utah Copper Co. became effective on January 1, was tendered a farewell dinner party at the Alta Club at Salt Lake City on December 22. C. T. S. Parsons, assistant cashier of the company, has been promoted to the position of cashier.

Thomas M. Skinner Jr., consulting metallurgical and chemical engineer of Douglas, Wyoming, is covering extensive research and examination work upon some of the natural deposits of California, including Owens Lake, at which place he installed a caustic soda and potash plant during the War.

Obituary

Benjamin Holt, president of the Holt Manufacturing Co., died at Stockton, on December 5. He had always been a man of great vigor, fond of hard work, and up to his last illness, had been constantly engaged in inventive and creative work connected with 'Caterpillar' tractors, Holt combined harvesters, and other machines originally invented by him. He was born in Merrimac county, New Hampshire, on January 1, 1849. His early education was in the public schools, later attending an academy at Tilton, New Hamp-

shire, and a Baptist institution at New London. The Holt Manufacturing Co. was incorporated at Stockton in 1892; Benjamin Holt was the inventive genius of the organization, and his name has become known throughout the world as a pioneer and leader in the design, invention, and building of new, important, and vital types of agricultural and road machinery. He invented the self-propelled combined harvester, a combination of tractor and harvester, the most effective grain-handling machine ever built. From the necessity of providing a surer traction for soft soils, Benjamin Holt gave the world his master invention, the track-laying type of tractor bearing his name, and now known the world over by the Holt trade-mark 'Caterpillar'. The world-wide prominence into which 'Caterpillar' tractors came over a decade ago, brought about the establishment of the Peoria factory in 1909, and Benjamin Holt was intensely interested in everything pertaining to the development of this big insti-

Benjamin Holt

tution as well as the parent plant at Stockton, California. Due to his pioneering work, the 'Caterpillar' was established as a commercial success and was available for military needs with the outbreak of the War in 1914, when it was adopted by the allied governments from among all the world's tractors for artillery and supply transportation. Those tractors brought about the creation of 'tanks', and Benjamin Holt has been given official credit by governments, and by the public everywhere, as the inventor of the 'Caterpillar' tractor which made the tanks possible. As time passes, and the great forces of the War are seen in their true perspective, the world will feel it owes a particular debt of gratitude to Benjamin Holt, whose inventive skill and genius brought the 'Caterpillar' and the 'tanks' into existence. Benjamin Holt, however, never conceived the building of a military machine as such, but invented the 'Caterpillar' tractor, and strived constantly to improve it, for everyday farming and road use. He was a respected citizen, an honored Californian, and an inventor whose ingenuity proved of value to the entire world.

THE METAL MARKET

METAL PRICES

San Francisco, December 28

Aluminum-dust, cents per pound	65
Antimony, cents per pound	7
Copper, electrolytic, cents per pound	14
Lead, pig, cents per pound	5
Platinum, pure, per ounce	\$85
Platinum, 10% iridium, per ounce	\$125
Quicksilver, per flask of 75 lb.	\$50
Spelter, cents per pound	8
Zinc-dust, cents per pound	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

December 27.—Copper is inactive but easy. Lead is stagnant and lower. Zinc is dull and declining

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE EDGE BANK AND FOREIGN TRADE

Objections to the formation of the \$100,000,000 bank, under the Edge Act, are largely due to misunderstanding of its objects, powers, and modus operandi. Many exporters and business men are under the impression that the Edge Bank will lend up to \$1,000,000,000 to exporters, farmers, manufacturers, etc.—in fact, anybody or any corporation that may want a long-time credit. This, of course, is not the purpose. Although it has broad powers, bankers say its principal business will be confined to issuance of debentures, bonds, and promissory notes designed primarily to promote international business.

Fear that securities might be offered that are not adequately protected, appears unfounded. The law provides that each issue of debentures, etc., must be submitted to the Federal Reserve Board for approval before it may be offered. Bankers believe no better guarantee could be offered the investor. They point out that the Federal Reserve Board has been severely criticized for its conservative regulations, but never for taking improper risks. Therefore, when the Reserve Board approves an issue, the public need have no hesitancy in investing, with entire confidence in the soundness of the security.

A banker who thinks the new bank will be one of the most constructive forces in the business world says: "The new bank will be the most powerful factor in the export business. It will be big enough to command the best brains in the country. It will have stockholders all over the country. Every State will be represented. Every stockholder will be a 'booster' for the loans, and probably most of the subscribing banks will be selling agencies. It will, therefore, represent the most efficient selling force for investments ever organized in peace times."

"The new institution is not being organized to benefit any one business or section. Its favorable influence will be felt in every community in the United States. It will be felt, in a limited way, the world over. Not a country but needs some assistance. Germany needs low-grade cotton, copper, etc., in large quantities. The objection that the allies have a prior lien on all Germany's productive powers is not sound. If we supply the raw material, there is no good reason why we should not be absolutely protected, because there is no other way Germany can produce a surplus to pay her debts. If the Allies prevent Germany from getting raw material they will themselves make it absolutely impossible for Germany to pay any indemnity, and they know it very well. Their only hope lies in the renewal of prosperity in the one-time Empire."

"The export situation, with regard to South America, shows no improvement. South Americans want our goods and have ample security to give us, but under present conditions we have no adequate facilities for financing long-term credits. Practically all efforts of the Edge bank will be directed toward correcting this deplorable export situation, because the law provides that it cannot conduct business within the United States except as incidental to international business. This is a time for co-operation. Every bank in the country should do its share toward bringing export business back to 'normalcy'. They can do that by promptly subscribing to the stock and then by 'putting their shoulders to the wheel' setting business moving again."

MONEY AND EXCHANGE

Foreign quotations on December 28 are as follows:

Sterling, dollars: Cable	3.50 1/2
" Demand	3.51 1/2
France, cents: Cable	5.85 1/2
" Demand	5.87 1/2
Lire, cents: Demand	3.39 1/2
Marks, cents	1.41

Eastern Metal Market

New York, December 23.

The markets are all without feature or activity and the price tendency is downward.

Odd lots of copper are going at concessions but real active demand is absent.

The tin market is nominal in the absence of any business, real or speculative.

Lead has again declined to new low levels for the year.

Zinc has receded to nearly the level of three or four weeks ago.

Antimony is quiet and unchanged.

IRON AND STEEL

The relation between the Steel Corporation's scale of operations and the average of leading independent companies has not changed from 85 to 90% for the former and 40 to 70% for the latter. There is wide variation in the activities of independent producers, the smaller companies faring worse. Some of the latter have a complete shut-down, but would start up on the accumulation of a few days' orders. The estimate of a 50% average at independent mills in the first quarter of the new year is not uncommon.

Definite announcements of wage reductions have been made at Johnstown and Coatesville, Pennsylvania; Wheeling, West Virginia; and Buffalo; generally about 20%, with elimination of overtime. No reductions have been made at Chicago or at Youngstown thus far, but January will bring many announcements.

The amount of new business coming to the books of the mills is under-estimated in some current reports. Naturally, it is for early delivery, but so many consumers and dealers are running on small stocks that producers continue to hear from them. Such week-to-week buying is to be expected for some months.

The blowing-out of blast-furnaces continues, seven or eight stacks being reported this week that have just stopped or will be out by the end of the year.

Welch makers of tin-plate are negotiating for a large Canadian order, according to our cable advices. British prices for ship-plates, boiler-plates, and steel hoops have been reduced. Business is at a low ebb throughout the British industry.

COPPER

The market continues very dull. There are frequent sales of small quantities to Europe and foreign countries, but domestic demand is exceedingly light and is being satisfied by a few producers or dealers who need the cash. One sale of 500 tons of electrolytic is noted at 13.50c., New York, for early delivery. It is stated that as low as 13c. can be done easily for December. Large producers are quoting 14c., New York, but will sell under this if a desirable order is presented for early delivery and for the entire first quarter, but not for March only. Lake copper is nominal at 13.75c., New York, for early delivery, but there is no demand. Consumers are not buying as the year closes and no purchasing on any scale is looked for until some time in January. It is the conviction of some in the trade that prices higher than 14c. will not be realized for some months at least.

TIN

The authorities in the Federated Malay States have again and for the third time in less than three weeks fixed a minimum price for tin, this time at an equivalent of £236 c.i.f., New York, as against £243 a week ago and £226 in the first instance. These changes have unsettled the market here and made a bad situation worse. Consumers and dealers as well as importers are in the dark as to what the Far Eastern gyrations mean. Consumers and dealers remain out of the

market and outside of the transactions noted a week ago on the New York Metal Exchange, there has been no business and prices are nominal. Yesterday spot Straits was quoted at 34c., New York, around which level it has hovered the whole week. The London market is lower with yesterday's quotations at £205 5s. for spot standard, £210 for both future standard and spot Straits, all of which are £6 to £7 lower than a week ago. Arrivals thus far this month have been 2385 tons with 1925 tons reported afloat.

LEAD

The American Smelting & Refining Co. late on Monday again reduced its price to more nearly conform to the outside market; the price is now 4.75c. both New York and St. Louis, against 5c. last week. The outside market has generally receded until yesterday lead for early delivery was obtainable and had sold at 4.60c., New York and St. Louis. The parity of the two districts is due to the possibility of competition of imported lead because of the weakness in the London market. There has been some buying since this market reached the 5c. level, but the volume has not been heavy. It is admitted that so far as stocks are concerned lead is in a better position than copper or zinc.

ZINC

The London market has measurably weakened in the last week or 10 days and this has had its effect here. Prices have declined until the New York and St. Louis quotations are again on a parity, due to the fact that foreign zinc has been offered as low as 5.70c., seaboard, duty paid. The imported zinc is not so much of a factor in this market as in the case of imported lead because some buyers prefer not to use it. Consumers are not buying nor are producers selling at present below-cost prices except where and when necessary. An upturn in the London market is looked for soon, in responsible quarters here, as stocks are not large and are in strong hands. We quote the market for prime Western for early delivery at 5.75c., New York and St. Louis, with domestic metal bringing 6.25c., eastern delivery.

ANTIMONY

This market is dull and unchanged with wholesale lots for early delivery quoted at 5.50c., New York, duty paid.

ALUMINUM

The leading maker's quotation for wholesale lots of virgin metal, 98 to 99% pure, is unchanged at 32.90c. f.o.b. producer's plant, while the same grade, largely of foreign origin, is quoted at 23 to 25c., New York.

ORES

Tungsten: The market is devoid of interest or activity, inquiries being limited to small proportions and resulting in no business. Quotations are nominal at \$4 per unit for Chinese ore and at \$4.50 per unit for Bolivian. The ferro-tungsten market is inactive and unchanged.

Molybdenum: There is no business and no prices are available.

Manganese: In the absence of any demand to test the market, high-grade ore is quoted nominal at 40c. per unit, seaboard, but it is believed that 35c. per unit could be done.

Manganese-Iron Alloys: There has been no real test of the ferro-manganese market where quotations are nominal at \$150, delivered, for the American product and \$170, seaboard, for the British, but it is confidently felt that a basis of \$125, seaboard, could be done. The British market is now at £33 per ton for export. Spiegeleisen, 19 to 22%, is quoted at \$60, furnace, but it is probable \$55 could be done at least on re-sale material. There are a few inquiries for both alloys before the market.

Book Reviews

Lead. Including Lead Pigments and the Desilverization of Lead. By J. A. Smythe. 115 pp., ill., index. Sir Isaac Pitman & Sons, Ltd., New York and London. For sale by 'Mining and Scientific Press'. Price, \$1.

This is one of a series of small volumes on technical subjects, non-technically treated, that is being published by Pitman & Sons. The history of lead mining and smelting; the modern methods of treating the ores of lead; the uses of lead, its alloys, and its compounds are discussed in an entertaining and instructive way. It gives an excellent idea of the operations necessary in the production of lead without going deeply into chemistry and physics.

The Theory of Machines. By Robert F. McKay. Second edition. 431 pp., ill., index. Edward Arnold, London. For sale by 'Mining and Scientific Press'. Price, \$6.

This book is perhaps best described to the American engineer and mechanic by stating that it covers practically the same field as Smith and Marx's 'Machine Design', and in about the same way. It is well-written and well-illustrated. However, a foreign technical book, even one published in Great Britain like the present volume, must, at least in minor details, exhibit differences in nomenclature and practice from that current in America. Under such conditions, the American engineer, unless the foreign book is notably superior in other features, will usually prefer one 'made in America'. In considering the present volume, this is the only important drawback that we can see.

Pumping by Compressed Air. By Edmund M. Ivens. Second edition. 254 pp., ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

The second edition of this book differs from the first, which appeared six years ago, in the addition of several illustrations and pages of text at various points. The book opens with a brief discussion of the general subject of pumping by compressed air, touching particularly upon various relatively uncommon methods. Then the air-lift and its application to pumping are considered, as well as the various commercial systems based upon it. Several chapters are also devoted to the hydraulic and thermo-dynamic theory upon which pumping by compressed air is based, and there are chapters discussing the compressor itself, and the design of an entire plant. The book will be useful to anyone engaged in pumping with compressed air.

Topographic Maps and Sketch Mapping. By J. K. Finch. Pp. 170, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

Interest in maps, and particularly topographic maps, has been stimulated, like interest in so many other subjects, by the War. The treatment in the present volume is non-technical and can be followed readily by the layman who has only the most elementary knowledge of mathematics. The book will be useful principally to two general classes of readers; first, men and women that use topographic maps but who do not know how to get the maximum benefit from them, and second, students engaged in learning to make a map that will be of maximum benefit to the user. The book is therefore appropriately divided into two main parts, Map Reading, and Sketch Mapping, besides a short additional chapter on Landscape Sketching. The discussion of map reading covers three chapters entitled, respectively, What a Topographic Map Shows, How to Get Certain Information from a Map, and Use of Topographic Maps in the Field. Part II, on Sketch Mapping, is similarly divided into Topo-

graphic Drafting, Flat Mapping, and Contour Mapping. The appendix contains a descriptive list of the principal topographic maps of the world, suggestions for a course in map reading and sketch mapping, and a bibliography, the first of the three divisions being particularly valuable.

Modern Welding Methods. By Victor W. Page. 278 pp., ill., index. Norman W. Henley Publishing Co., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

The art of welding in its various branches has made such remarkable progress in the past few years that it has been difficult for the published matter to keep pace with it. The present volume may be said to be a very creditable attempt to catch up. After an introduction discussing the general features of the various methods of joining metals, the properties of the common metals are considered. The next three chapters are devoted to gas welding, considering in turn the gases used, the apparatus, and the general methods and technique. The next chapter considers electric welding, both resistance and arc, and the next thermit welding. Then comes a chapter on soldering and brazing processes, and the final chapter deals with forge-welding and with the heat treatment of steel. The book will be useful to anyone engaged in welding, directly or indirectly.

Practical Trade Mathematics. By James A. Moyer and Charles H. Sampson. 169 pp., ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$1.50.

If all our mechanics had a common-school education and our system of common-school education was really practical, there would be relatively little need for a book of this kind. Things being as they are, however, the book should be useful to many mechanics, who have come to realize their need of additional knowledge of mathematics. The book covers arithmetic and some plane geometry, but does not discuss either algebra or trigonometry. This latter appears to us to be a mistake. An explanation of the sine-bar, for instance, would have been welcome. Problems drawn from the practice of the various trades are used freely throughout the book to illustrate the discussion, and theoretical considerations are kept in the background as much as is feasible.

Powdered Coal as a Fuel. By C. F. Herington. Second edition. Pp. 324, ill., index. D. Van Nostrand Co., New York. For sale by 'Mining and Scientific Press'. Price, \$4.50.

Both the theory and the practice of the use of powdered coal have progressed so rapidly during the two years since the appearance of the first edition of this book as to justify a second edition, in which considerable new material has been added as well as the old material revised. After a general discussion of the burning of powdered coal, the various special applications are considered in detail, chapters being devoted to cement and lime kilns, annealing, air, and other furnaces, and core-ovens, as well as the use of powdered coal as a fuel under boilers for stationary, marine, and locomotive engines. The prevention of explosions, which, the author states, is entirely feasible, is also considered. A complete bibliography, both of books and of magazine articles, is included. The book will be useful to anyone who uses, or who is considering the use of, powdered coal.

Engineering Electricity. By Ralph G. Hudson. 186 pp., ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

This book, as the preface states, "was written primarily for technical students not specializing in electrical engineering", but it would also be useful to many engineers, practising other branches of the profession, but feeling the need

of greater knowledge of electricity and its applications than they possess. The chapter headings, which give a general idea of the scope of the work, are as follows: Direct-Current Circuits; Electro-Magnetism; Electro-Magnetic Induction; The Direct-Current Dynamo; Direct-Current Measurements; Alternating-Current Circuits and Measurements; Three-Phase Currents; The Alternating-Current Transmission-Line; The Synchronous Generator; The Synchronous Motor; The Synchronous Converter; The Mercury-Arc Rectifier; The Transformer; The Three-Phase Induction Motor; and The Alternating-Current Series Commutator Motor. A useful feature of the book is a 40-page appendix of various kinds of electrical apparatus. Like so many technical treatises, its usefulness would be materially increased by the addition of a few pages giving definitions of every symbol used in the book and a collection of all the formulas derived in various parts of the text.

The Practice of Lubrication. By T. C. Thomsen. Pp. 602, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$6.

Few owners or operators of machinery realize the amount of loss possible through faulty lubrication and wrong selection of lubricating-oil. Those, however, who wish to have a basis for the study of their lubricating problems will find this book of great value. It begins with several chapters devoted to the various kinds of lubricants, including mineral, animal, and vegetable oils and greases, as well as graphite and other special lubricating mediums. Lubricating appliances and the various types of bearings are then considered. Then come several chapters on the lubrication of the principal kinds of machinery, a valuable feature of this part of the discussion being a set of lubrication-charts, one for each type of machine. Chapters are also devoted to oil recovery and purification, to oil storage and distribution, and to cutting-lubricants. In fact, the book is one of the most complete treatises on the subject that has appeared.

The Autobiography of Andrew Carnegie. 372 pp., ill., index. Houghton Mifflin Co. For sale by 'Mining and Scientific Press'. Price, \$5.

This is the life story of a remarkable man, written by himself in an easy conversational style, without either affectation or false modesty. He tells of his birth and childhood in his beloved Scotland and of the business disasters that impelled the family to start anew in America. His work as a telegraph messenger boy and then as an operator was the means of bringing him into contact with, and later into the service of, Thomas A. Scott, division superintendent for the Pennsylvania railroad. The well-known story of his assumption of authority during an emergency in Scott's absence, and without technical justification, is told, although he does not appear to attach so much importance to the incident as do some of his biographers, who appear to regard it as the turning point of his career. The years of his service with the Pennsylvania, broken for a brief period by his work for the Government as associate director of railroad operations during the Civil War, were marked by several promotions, and the way was open for further advancement. However, his railroad experience had convinced him of the possibilities of the iron industry, and a few ventures, started as a sideline, soon demanded his entire attention. At first his activities were confined to the rolling of rails and bridge-members, the former, in particular, being mainly imported from England at that time, the late 'sixties. Soon, however, the business expanded to the rolling of other products, and to the operation of blast-furnaces, iron-mines, and coke-ovens. It will be a surprise to most readers to learn that the Carnegie concern was the first in America to employ a chemist in connection with its blast-furnace operations. Amusing incidents are told of the mistakes of his competitors, who were

preparing their furnace-charges by rule-of-thumb, and who were paying high prices for ore shown by analysis to be of poor quality. Here we have one of the most important reasons for his success, namely, his determination to have the best machinery and the best methods, not only in the manufacturing but also in the accounting end of the business. What this latter meant in those days is indicated when he tells us that many of his competitors had no system of cost-accounting whatsoever. More important, however, in the success of the Carnegie companies was the faculty of their leader, which he so frequently mentioned, to gather about him more able men than himself, a statement that we cannot accept as strictly true if we believe that this very faculty shows the highest form of ability. A necessary complement of this faculty was the willingness to reward generously the men who worked with him. His attitude toward labor was unquestionably dominated by a desire to be fair, and he points with pride to the years of industrial peace at his plants, broken only by the Homestead strike. This strike was one of the great griefs of his life, and he devotes a chapter to a straightforward discussion of it, affirming his belief that on the main point at issue the men were wrong, while admitting that mistakes of judgment were made by the company. His retirement from the steel business, and his successful efforts to give away nearly, although not quite, all his money are described, together with a little discussion of some of his activities in the distribution of his wealth. As in most autobiographies, perhaps the most interesting feature is the glimpses of the writer's intimate friends, who included, in this case, such widely different men as Gladstone, Bryce, Matthew Arnold, John Morley, Herbert Spencer, Blaine, Harrison, and Mark Twain, as well as many others. These reminiscences are enriched and enlivened by many anecdotes, of which we have space for only one. It concerns the German superintendent of the rolling-mills, William Borntraeger by name, who took a vacation for the purpose of going to Germany and bringing home a bride. When he started, Carnegie said, "I suppose your sweetheart is a beautiful tall young lady". Borntraeger replied, "Vell, Mr. Carnegie, she is a leetle stout. If I had the rolling of her, I give her yust one more pass".

Handbook of Building Construction. By George A. Hool and Nathan C. Johnson. In two volumes. Pp. 1444, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$10.

This is a book for the architect, the structural engineer, and the building contractor. It covers the design and construction of the principal kinds of buildings, from the smallest to the largest, of whatever material, and including the mechanical and electrical equipment. In the preparation of the material, the principal authors have been assisted by 46 engineers and architects, specialists in particular lines. The text is illustrated by a large number of line-drawings and many mathematical tables are included. The book is divided into three parts. Part I, on Design and Construction, is further subdivided as follows: Elements of Structural Theory, Designing and Detailing of Structural Members and Connections, Structural Data, General Designing Data, Construction Methods, Construction Equipment, and Building Materials. In Part II, on Estimating and Contracting, the chapter-headings are Estimating Steel Buildings, Estimating Concrete Buildings, Architectural Practice, Contracts, and Specifications. Part III, on Mechanical and Electrical Equipment, is divided as follows: Heating, Ventilating and Power, Water-Supply Data and Equipment, Sewage-Disposal, Waterless Toilet-Conveniences, Plumbing and Drainage, Electrical Equipment, Electric Lighting, Gas Lighting, Gas Fitting, Elevators, Mechanical Refrigeration, Communicating Systems, Lighting Protection, and Vacuum-Cleaning Equipment.

DRIVE WITH THE DX 61

"THE DX-61 is Rugged, Simple in Design, has few Wearing Parts, Drills as Fast or Faster than its Nearest Competitor, and Does Not Grind the Drill Bits."

IN these words a Butte mine official summed up his findings on a test for drilling speed, air consumption, and wear on drill bits, conducted on seven different drifting drills.

Here are the figures:

	Sullivan DX-61	Nearest Competitor
Ft. drilled per min.823	.810
Average air used per ft. drilled (cu. ft.) . . .	1045	1356
Average wear on bits (inches).55	.068

In the Joplin district 33 drills of 5 types were run for 20 days. The DX-61 drilled 1074 feet, nearest competitor 686 feet.

The DX-61 cost \$00.00 for repairs, nearest competitor \$16.13 per machine.

These are samples of reports from mining districts all over the country.

If you need a big, fast, economical drifting drill, the DX-61 water jet hammer drill will do equally good work in your mine.

Bulletin 1370-I on request

SULLIVAN MACHINERY COMPANY.

123 So. Michigan Ave., Chicago,

580 Market St., San Francisco.

DOMESTIC SALES OFFICES:

Birmingham, Boston, Butte, Claremont, N. H., Cleveland, Dallas, Denver, Duluth, El Paso, Huntington, W. Va., Joplin, Juneau, Knoxville, New York, Pittsburgh, St. Louis, Salt Lake, San Francisco, Spokane.

FOREIGN SALES OFFICES:

Algiers, Brussels, Calcutta, Christiania, Durban, Natal, Havana, Lima, London, Madrid, Mexico City, Paris, San Juan, Santiago, Shanghai, Sydney, N. S. W., Tokyo, Toronto, Tunis, Turin, Vancouver.

SULLIVAN PRODUCTS

Air Compressors; Air Lift Pumps; Diamond Drills; All-Hammer Drill Sharpeners; Drill Steel Furnaces; Forge Hammers; Ironclad Coal Cutters; Rock and Hammer Drills; Quarrying Machinery; Contractors for Diamond Core Drilling.

Fairbanks Scales Type "S"

Track Scale for Accurate Carload Weights

Center suspension of load eliminates torsion. No projecting pivots—vertical adjustment on all bearings and connections—full clearances afford ample room for convenient examination and adjustment—weigh beam constructed with center suspension principle and continuous bearing pivots—positive self locking protected balancing device.

A Worthy Running Mate for Your Pride Machinery—

GANDY, the original stitched COTTON DUCK BELT!

Both for service and endurance, Gandy is a match for the best machinery in many industries.

It is especially able to tackle hard drives—outdoor drives—drives where oil splashes; where steam, acid fumes and grit abound.

From 15 to 27 years is the "Lifetime" of Gandy Belts.

They stand up because they have the stand-up stuff in their makeup—strong, firmly woven cotton duck in one piece construction—and impregnated with a secret oil compound.

The Gandy Engineering Department stands ready to fit Gandy Belting to any of your equipment. Send in your specifications—both power and conveyor—and your needs will have prompt attention.

BELTS

—taking and trusting

Confidence is mutually sustained among men engaged in the world's industrial work by the good performance of industrial tools.

Inventors and manufacturers meriting confidence produce what the user can take and trust. In the realm of mining, for example, labor-saving devices and laboratory specialties are important hostages of the house that sponsors them.

For more than half a century, our products have gone resolutely a-field. They are the hostages of that entire confidence which our institution has established throughout the mining realm.

Our broad experience—our extensive facilities for filling your urgent needs—are gladly placed at your entire command.

Under this heading announcements may be made of new and second-hand machinery or supplies, for sale or wanted. The cost is 5 cents per word, including address. Minimum charge one dollar per insertion. Remittances must accompany order. Copy must be received by Saturday for the following week's issue.

ALLIS-CHALMERS ball-mill, capacity 40 tons, unused, \$3300; aerial tram, Broderick-Bascom, continuous type, capacity 10 tons, 3600 ft., complete with track cable, unused, \$4000. Gibson's Limited, No. 1 Alexander St., Vancouver, B. C. 1-29

FOR SALE—One 150 H.P., Type "R-E", Fairbanks-Morse vertical oil engine and generator. Same has just been overhauled by the manufacturer. Can make immediate delivery. For information and price, address Wisconsin Zinc Company, Platteville, Wisconsin. tf

OPPORTUNITY—Diamond drilling on a new basis of cost, saving you one-half to one-quarter over present methods. Guaranteed work with best up-to-the minute equipment, efficient and experienced help. Long experienced and enthusiastic customers. Write for information. H. D. Staley, 229 Lick Bldg., San Francisco. tf

LEARN HOW to properly sharpen and temper mine and quarry tools; booklet by mail \$1. E. W. Liljegan, Medford, Oregon. 12-25

FOR SALE!

One Layne & Bowler Deep Well Type Vertical Centrifugal Pump. Capacity 3000 G.P.M. at 760 foot setting. Pump has patented oil thrust bearing head and high efficiency impellers. Direct connected to 900 H.P. 1200 R.P.M. 60 cycle, 3 phase, 2300 volt General Electric vertical motor, complete with all starting appliances. The unit was specially built for mine work and can be installed in a 5x5 shaft or compartment, is brand new and has never been installed.

One Layne & Bowler Deep Well Type Vertical Centrifugal Pump. Capacity 2000 G.P.M. at 190 foot setting, patented oil thrust bearing head, high efficiency impellers. Direct connected to 150 H.P. 1200 R.P.M. 60 cycle, 3 phase, 2300 volt General Electric motor. All equipment adapted for mine work. The shafting, tubing, discharge column and oil bearing head was in service about thirty days at a different location. The pump proper and motor have never been turned over.

POSITIONS WANTED

The cost of advertising for positions wanted is 2 cents per word, including address. Minimum charge 50 cents per insertion. Replies forwarded without extra charge. Remittances must accompany order. Copy must be received Saturday morning for the following week's issue.

ELECTRIC POWER SUPERVISOR, west coast of Mexico, desires position about January 15; twelve years maintenance and construction experience mills, mines and smelters; desires position in charge of steam, lighting and power equipment of mining concern. Mexico preferred; references; minimum salary \$2500 per year and expenses. Address PW 548, Mining and Scientific Press. 1-1

METALLURGIST, age 35, married; as superintendent or assistant in smelter or refinery; experience covers 11 years in smelters, operation of lead blast furnaces, refining of copper and lead bullion; capable, aggressive executive; correspondence invited and personal interview if desired; will go anywhere; immediate acceptance; salary open. Address PW 539, Mining and Scientific Press. 1-1

MECHANICAL AND STRUCTURAL DRAFTSMAN available January 1; technical training, 8 years experience in lead and copper mine, mill and smelter work; high-class references. Address PW 540, Mining and Scientific Press. 1-8

MINE SUPERINTENDENT, formerly in charge of copper mine, desires position; years of experience; single; Spanish spoken. Address PW 543, Mining and Scientific Press, 31 Nassau St., New York City. 1-15

MINE CHIEF CLERK wants position; years of experience with representative companies; single, age 45; can handle entire office work of mine employing 100 to 150 men, including cost sheets; speaks Spanish; minimum salary \$350; references given. Address PW 541, Mining and Scientific Press, 31 Nassau St., New York City. 1-15

METALLURGICAL ACCOUNTANT wants position; long experience; single, age 45; speaks Spanish; references given. Address PW 544, Mining and Scientific Press, 31 Nassau St., New York City. 1-15

MINE AND SMELTER ACCOUNTANT desires position with company where large opportunity exists; speaks Spanish. Address PW 543, Mining and Scientific Press, 31 Nassau St., New York City. 1-15

POSITION WANTED by research chemist competent to develop new methods and chemical processes for metal extraction. Address PW 545, Mining and Scientific Press. 1-23

FLOTATION PLANT and mill foreman, 20 years general experience in milling; 6 years in flotation work; specialty silver ores; up-to-date practice and high extraction. I can increase your tonnage and general efficiency; minimum salary \$300. Address PW 547, Mining and Scientific Press. 1-1

MINE ACCOUNTANT, extensive experience, 20 years in gold and quick-silver work; executive experience; wants position Mexico, West or South-west; age 41, married, no children; speaks Spanish; 5 years practical experience underground, 1 year mill work; health excellent; best of references; employed at present. Address PW 536, Mining and Scientific Press. 1-15

MINING ENGINEER, technically educated, desires position as manager; 20 years broad experience in management of mining and milling precious and commercial metals; thoroughly qualified for exploration, surface and underground development; speaks Spanish. Address PW 511, Mining and Scientific Press. 1-8

MILL SUPERINTENDENT, many years experience in milling and cyanidation in different parts of the world, desires position in charge of plant; graduate, Spanish; will go anywhere; foreign preferred. Address PW 529, Mining and Scientific Press. 1-1

RESEARCH CHEMIST, experienced in non-ferrous metallurgy, leaching, electrolytic copper and zinc; at present employed, open for engagement, research or as chief chemist. Address PW 531, Mining and Scientific Press. 1-22

STORE-ROOM MAN or timekeeper, experienced bookkeeper, age 38, desires position; no objection to Mexico or Canada. Wife good cook. Address PW 528, Mining and Scientific Press. 1-1

ACCOUNTING-AUDITING SYSTEMS installed, income tax reports, books opened, closed, balanced; small sets kept efficiently. We specialize in mine accounting and systems. J. W. Reno & Co., 584 Mills Bldg., San Francisco. Phone Sutter 7046. 1-29

MINE SUPERINTENDENT or assistant superintendent now open for engagement; technical man; ten years experience mining and construction work; single; speaks Spanish; go anywhere; minimum, \$250 and expenses. Address PW 521, Mining and Scientific Press. 1-1-21

GRADUATE MINING ENGINEER, age 37, as superintendent or assistant; 15 years experience in mining, underground exploration, construction, and development of orebodies; low costs and efficient engineering; speak Spanish; at present employed. Address PW 513, Mining and Scientific Press. 1-8-21

MINING ENGINEER, ten years manager and superintendent in Mexico; open for position January 1; at present on Pacific Coast. Address PW 524, Mining and Scientific Press. 1-8

MINING AND SCIENTIFIC PRESS wants a permanent circulation representative in every mining community in the world. Replies will be held confidential if desired. Address The Manager, Mining and Scientific Press.

FOR IMMEDIATE DELIVERY

AGITATORS:

- 3—24"x12" Dorr agitators; with or without tanks.
- 6—16"x36" Pachuca agitators.
- 6—7"x18" Pachuca agitators.

AIR RECEIVERS:

- 1—42"x 9".
- 1—30"x 8".
- 1—60"x24".
- 1—48"x14" 6".
- 1—48"x20".
- 5—15"x4".

ASSAY OFFICE MATERIAL:

- 1—Thompson Button balance.
- Several sample crushers and pulverizers.

BALLS—GRINDING:

- 2" to 5" semi-steel.

BLOWERS:

- 1—No. 6 Roots blower, 3800 cu. ft., displacement 5 lb. pressure with 100 H.P. Westinghouse motor.
- 2—10" blowers.

BOILERS:

- 1—28"x8" portable.
- 1—42"x9" mounted.
- 1—25 H.P. locomotive type.

CABLEWAY:

- 1—radial cableway 1790 foot span, complete with motor and all equipment.

CABLE—STEEL:

- 2 reels each 1900', 1" diameter, Roebling's Hercules Blue Center steel cable. Good condition.
- 1 reel 450' steel cable, ½". Good condition.

CARS—ORE:

- 6—13 cu. ft.—18" gauge. NEW.
- 2—20 cu. ft.—18" gauge.
- 24—50 cu. ft.—24" gauge.
- 5—1 ton Truax end dump cars.
- 2—2 ton side dump cars.

CHAIN BLOCKS:

- 2—¾ ton Y & T triplex.

CLASSIFIERS:

- 1—14"x24" Dorr Simplex.
- 1—45" Akins.

COMPRESSORS—AIR:

- 1—10"x12" Sullivan "WG-3" straight line.
- 1—8"x12"x15" Rix two-stage C.C. belt driven.
- 1—13"x10" Ingersoll-Rand double cylinder, low pressure.
- 1—12"x12" Ingersoll-Rand, belt driven.
- 1—16"x10" Clayton single cylinder, low pressure.
- 1—32"x18 ½"x24" Ingersoll-Rand compound, Class "PE-2", 3175 cu. ft. displacement at 150 R.P.M., direct connected to 450 H.P. General Electric synchronous, 3-60-440 motor.
- 1—15"x24"x36" Nordberg two stage, belted to 200 H.P. Westinghouse motor.

CONCENTRATING TABLES:

- 1 double deck Deister Simplex slime.
- 3 single deck Deister Simplex sand.

CONVEYOR:

- 1—48"x16" belt conveyor with new belt take ups, troughing rollers, return idlers and 4"x6" wooden frame.

CRUSHERS:

- 1—No. 3 Austin gyratory.
- 1—No. 7 ½-E Allis-Chalmers Gates gyratory.
- 1—Laboratory crusher.
- 1—10x18 Joshua Hendy Blake type.

ELEVATOR:

- 1—24' center belt and continuous bucket elevator.

FEED GATES:

- 7—18"x36" high, complete with guides, hand wheel, rack and pinion.

FILTER:

- 1—12"x10' Oliver filter, complete with pumps, vacuum receiver and moisture trap.

FURNACE AND CRUCIBLE:

- 1—Monarch tilting furnace and crucible.

HOISTS:

- 1—7x10x43 Hendrie & Bolthoff steam hoist.
- 1 each 12 H.P., 20 H.P., 25 H.P., Western gas hoists. NEW.

LOCOMOTIVE—STEAM:

- 1—Baldwin Standard 6 wheel switch engine, about 35 tons.

MILLS:

- 1—8"x22" Hardinge conical ball mill, complete with Titanite liners and chrome steel balls.
- 1—4"x10' Power & Mining Machinery Co.'s wet grinding tube mill.
- 3—4 ½" ten ton Kinhead mills, top driven.
- 5—6"x16" Allis-Chalmers Standard wet grinding tube mills.

MOTOR GENERATOR SET:

- 1—680 H.P. synchronous motor generator set, complete with booster, exciter, switchboard, switches, etc.

MOTORS AND GENERATORS—D.C. AND A.C.:

- We have a large stock constantly on hand of all sizes and makes and for all purposes. At present from 150 H.P. down to 3 H.P.

PANS:

- 1—3 ½' clean-up pan.

PELTON WHEELS:

- 1—1 ½" wheel.
- 1—2" wheel.

PUMPS:

- 1—4 ½"x8" Gould triplex.
- 1—4"x8" " "
- 1—7"x8" " "
- 1—3"x4" " "
- 1—3 ½"x7" Aldrich single acting.
- 1—6"x9" Aldrich triplex.
- 1—8"x10" Dean triplex single acting with motor.
- 1—4" Frenier sand pump.
- 1—5 ½"x3 ½"x5" Fairbanks-Morse double acting pump.
- 1—2" Jackson centrifugal, 3-stage.
- 2—Advance boiler feed pumps, size No. 323.
- 1 each, Cameron sinker, No. 5, No. 7, No. 9-B.

RAILS:

- 8 lb., 12 lb., 16 lb., new supply, just received.

STAMP MILL:

- 8—5 stamp batteries, complete.

TANKS:

- 8—15"x36" Redwood. NEW.
- 3—10"x 8" NEW.
- 6—7"x18" " USED.
- Large stock of wooden tanks, all sizes, in good condition.

THICKENERS:

- 2—24"x8" Dorr thickener mechanisms and Redwood tanks.

TRANSFORMERS:

- 1 each 25, 10, 10 K.W., 6600/440.
- 2 each 10, 7 ½ K.W., 6600/440/200/110.

The World's Greatest Belt Lacing

ALLIGATOR STEEL BELT LACING

TRADE MARK REG. U.S. PAT. OFFICE

Consider carefully the 100 per cent efficiency of Alligator Steel Belt Lacing in satisfying your requirements. You will find it best on every kind of leather, cotton, rubber or balata belt.

Best for Every Service

Everywhere in Industry, where belting is required, Alligator Steel Belt Lacing is known and preferred.

Short, flexible joint insures smoothness of operation. Sectional Steel Rocker Hinge Pins (patented) form frictionless "rocker" for the flexible joint. In damp or heavy work, where other lacing pulls out, Alligator Steel Belt Lacing holds.

Simple, Strong, Economical —Preferred by All Who Know It Makes a Perfect Joint

In a working time of less than three minutes, the average belt can be laced with Alligator Steel Belt Lacing. No special skill or training needed. No tool but a hammer to insure a perfect joint. Consider this saving in help, time and money over other methods of lacing.

Alligator Steel Belt Lacing saves the belting because the pull comes against the edge of the teeth and not the flat. It becomes a permanent part of belt—does not pull out—and replacements even in hardest use are practically unknown.

FLEXCO-LOK STEEL LAMP GUARDS

Produced in connection with our Alligator Steel Belt Lacing, and sold at a decided saving as a mechanically perfect guard.

In all sizes—standard brass or weather-proof sockets, with or without reflectors. Either portable or stationary types, with patent self-retaining lock screw or plain round head screws. Not stocked in London.

Hundreds of thousands of men the world over are now recommending and using no other lacing than Alligator—The World's Greatest Belt Lacing. It will be a big saving and a wonderful convenience for you. Use the coupon. Tear it off now. Write us at once.

GARRATT JACK HEAD PLUNGER PUMPS

Are Not Affected by
Muddy, Gritty Water

The cylinder has large clearance and the plunger is outside packed at the top. The suction and discharge valves are fitted with bronze taper seats and are easily exchanged by removing bonnets. The Jack Head works altogether on the down stroke; the pump rod is made to weigh just half the amount of pressure exerted on the plunger so that the load is equal and uniform at all times whether on down or up stroke. In this way

Balance Bob is Eliminated

thereby increasing the efficiency and materially reducing cost of installation. These pumps are made with capacities of from 30 to 500 gallons per minute and for elevations up to 600 feet.

use the

CEMENT - GUN
TRADE MARK

ers has done much to make them more contented and efficient during the present tense times of maximum production.

Credit for the success of this work should be given to the efforts of an efficient crew under the supervision of the local superintendent, Mr. Joseph Maize, and the general superintendent of operations, Mr. E. Cox. They both early foresaw the far reaching benefits that could be derived if the work proved a success and great credit is due them as the leading successful pioneers in the use of the cement gun in the bituminous coal fields. Mr. Cox is very enthusiastic over the results and expects to install similar equipment at an early date in the other mines of the company. The many mining men who have examined this work have pronounced it a great success and see a widely extended use made of the cement gun throughout the coal fields where trouble is experienced with bad roofs.

Salt
Lake
Mining
Review,
Jan. 30,
1919

The almost universal adoption of the "Cement-Gun" in coal mines since the time this article was written has vindicated the editor's contention—and metal mines are rapidly following in line.

There is no reason why the "widely extended use where trouble is experienced with bad roofs" which the "Cement-Gun" enjoys among coal mines should not be duplicated among metal mines.

Among the many reasons for the Cement-Gun's popularity is the fact that it repairs bad roofs PERMANENTLY.

(We Sell Traylor Mine Type Compressors.)

The BYRON JACKSON MINE STATION PUMP

is a self-contained unit, consisting of a twin six-stage, Centrifugal, Direct Connected Pump

It is fitted with flexible couplings and water-cooled, marine type thrust bearings.

We have shipped several pumps of this type during the past few months. Examples of capacities and heads are as follows:

225 G.P.M.	840' head	1750 R.P.M.
250 "	1020' "	1750 "
550 "	840' "	1750 "
450 "	1560' "	2300 "

We build these pumps for heads up to 2000

Submit your pumping problems to us. No obligation. Write today for Catalogue No. 71

YOUR OPPORTUNITY

YOU have often felt the need for a small, compact, light, and efficient air compressor, something of say 180 cu. ft. free air per minute to 100 lb. gauge pressure that could be lowered down your shaft at a pinch, or could be snaked around the surface and hooked up to a gas engine, motor, or belted to a countershaft.

Here it is, the Jackson Rotary. It fills the bill, and more.

Send for Bulletin 180-A.

Haul Without a Hitch

By hauling overhead, you control your output—the weather does not, neither do road conditions nor the moods of draft animals.

B & B Aerial Tramways

provide steady transportation at lowest cost per ton of material. No elaborate equipment—nothing to get out of whack.

Send for Catalog No. 45.

(Continued on page 52)

"Veribest" Air Hose is made of selected material that will stand up longer and stand more abuse than is found in ordinary manufacture.

"Neverleak" Couplings are connected and disconnected quicker than is possible with other types. They cannot become accidentally disconnected and can be connected in the dark without the use of a wrench.

A trial order of Cleco Fittings will convince you.

"Cleco" Hose Menders and Mender Clamps never wear out, can be quickly attached, insure a tight joint, and prevent hose from blowing off.

"Cleco" Air Seated Valves have but three parts—body, valve-plug and handle. There is no packing, as valve plug is air sealed. Has no angle turns in air channel and leakage is impossible.

SERVICE

Is what you want and what you get in *National Quality Tanks*, because they are honestly and expertly made from either Douglas Fir or California Redwood.

We manufacture all kinds, sizes and shapes of tank, for every conceivable purpose. Careful attention given to special installations.

Used by the United States Government and big mines everywhere.

We manufacture complete cyanide plants either standard or on special specifications.

MINE BOOKKEEPING

By ROBERT MCGARRAUGH

118 Pages

6 x 9

46 Illustrations

PRICE \$2.00

THIS book outlines a comprehensive system of records and accounts for mining operations of moderate dimensions. This system can be maintained at a minimum of office expense, and provides a practical method of cost-keeping. More than forty model forms are included as suggestions in keeping records and accounts.

Sent Postpage Prepaid. Order Now.

Price \$6.00

A book dealing with the various phases of oil geology, written in language free from needless technicalities. Of particular use to engineers, geologists, shareholders and investors.

Treats the following subjects:
The Origin of Petroleum; Processes of Formation; The Migration, Filtration and Subterranean Storage of Petroleum; Lateral Variation; Geological Structure; Indications of Petroleum; Natural Gas or Gaseous Petroleum; Oil-Shales and Torbanites; Stratigraphy; Location of Wells; Petroleum Prospects in Britain; Field Work (for Beginners); Indoor Work (for Beginners).

USE THE COUPON

MINING AND SCIENTIFIC PRESS,
420 Market St., San Francisco

Gentlemen: Enclosed find \$6.00 for which send me a copy of Craig's "Oil Finding", latest edition.

Wilfleys are used as Pilot Tables in Flotation

By this method high recovery in the flotation cells is constantly maintained

Wilfley Tables perform an important part in the treatment of complex ores by flotation. They act as indicators or pilot tables, taking products from various stages of the process and checking the work of the flotation machines.

At the plant of the Sunnyside Mining and Milling Company at Eureka, Colorado, Wilfley Tables are used for this purpose. A gold-silver-lead-copper-zinc ore is treated by selective flotation and results are continually tested on Wilfleys.

Several types of Wilfleys are made to meet every need; single deck, double deck, arranged for concrete or steel channel foundation, laboratory size or half size.

Write our nearest office concerning your concentrating problems.

The Mine and Smelter Supply Co.

DENVER

SALT LAKE CITY

EL PASO

NEW YORK OFFICE: 42 Broadway

T. A. RICKARD, Editor

IT appears that on December 22 the American Smelting & Refining Company, by Mr. Edgar L. Newhouse, made return to the petition of Mr. Eilers for a writ of mandamus. We find Mr. Newhouse's statement in the current issue of the 'Engineering and Mining Journal'. We reproduce it on pages 63 and 64 of this issue.

AT a time when a native of New York, of Spanish name and parentage, is described as the president of the Irish republic, it is amusing to note that the President of Mexico is stated to be the great-grandson of Michael O'Brien, an Irishman who became Miguel Obregon and then Obregon as soon as he had distinguished himself in the revolutionary war identified with the insurgency of Iturbide. Thus Alvaro Obregon is alleged to be the direct descendant of Mike O'Brien. Whether Mr. De Valera's pedigree leans on the Spanish or the Mexican side, we do not know, but General Obregon certainly looks Spanish enough to escape the suggestion of fitness to lead the Sinn Fein.

ESTABLISHMENT of a new metal-selling agency is announced by the firm of Guggenheim Bros. Henceforth the selling of the copper produced by the Utah, Chino, Ray, Nevada, Chile, Braden, and Kennecott companies will be in the hands of Guggenheim Bros. instead of being done by the American Smelting & Refining Company. The reason given is "a natural, if not inevitable, incident to the growth of industry". It is acknowledged that the Smelting company, in selling the copper of other companies, "had come to bear a responsibility greater than it was willing to assume". In any case, it was a responsibility that it had discharged with questionable success, if Mr. Karl Eilers is to be believed. Indeed, the announcement comes so soon after the disclosures made by him that the public is likely to make an inference not altogether complimentary to the gentlemen in control at 120 Broadway, New York.

IT was a pity that the President delayed his approval of the bill extending the time for assessment work; he signed it on the last day of the year. We received numerous telegrams from miners anxious to know what had been done. The text of the bill is as follows: "That the period within which work may be performed or improvements made for the year 1920 upon mining claims, as required under section 2324 of the Revised Statutes of the United States, is hereby extended to and including the

1st day of July, 1921, so that work done or improvements made upon any mining claim in the United States or Alaska on or before July 1, 1921, shall have the same effect as if the same had been performed within the calendar year 1920; Provided, That this act shall not in any way change or modify the requirements of existing law as to work to be done or improvements made upon mining claims for the year 1921."

GOLD MINING is discussed in several annual reports issued by officials of the Government. The Secretary of the Treasury says that the high cost of production has affected this industry unfavorably, but he thinks that, as the purchasing power of the dollar increases, the production of gold will become remunerative. A Solomon verily! The Secretary of the Interior recommends an increased appropriation for geological investigations in Alaska to encourage the mining industry in that Territory. Alaska has had plenty of geological investigations and they have been among the best of their kind. The Governor of Alaska favors a premium on gold to be paid to the producer and remission of royalties on coal-lands for the first five years. The Chief of Engineers of the Army recommends an appropriation of a million dollars to begin a ten-year program of road construction for the purpose of developing the mineral resources of Alaska. The building of roads is a first-aid to mining development and if done sagaciously is well worthy of endorsement. The same official expresses the belief that the prosperity of Alaska rests on "the vigorous virile miner and prospector". As the wife of the Mayor of New York said to the King of the Belgians: "Sir, you said a mouthful".

DEPRESSING statements concerning mining are the fashion at present, just because some of our friends are long in timidity and short in memory. Times of depression alternate with periods of elation, contraction follows expansion, the economic pendulum seems to have its swing in obedience to a law as insistent as that of gravity. For a change, and to hearten our friends, we may mention that Ontario, a Canadian mining region of no small interest and consequence, yielded \$35,920,418 in metallic products during the first nine months of 1920 as against \$27,875,713 in the corresponding period of 1919. These statistics have been issued recently by the Department of Mines at Toronto. Gold mining seems to be alive, for the production was \$8,735,768 in

1920 as against \$7,574,586 in 1919—that is, for the respective nine months. The mining of silver likewise shows some liveliness, for the production increased from \$7,898,220 in 1919 to \$8,435,088 in 1920. Evidently mining in Ontario is not dead, nor even dying.

MANUFACTURERS of mining machinery and equipment in the United States are more than holding their own in competition with manufacturers in Great Britain so far as their sales to the mines of the Witwatersrand in South Africa are concerned. In 1913 we supplied only 9.52% of the manufactured goods imported into South Africa as compared with 56% by the United Kingdom. During the War our proportion increased as a result of Britain's inability to spare many commodities, but it was expected that the return of peacetime conditions would restore approximately the former ratio. Such has not been the case. Whereas America furnished 13.87% of South Africa's imports in 1918, the corresponding figure for 1919 is 24.14% as compared with only 45.46% from the British Isles. These data are in respect of all manufactured products, including those used in the mining industry, but the ratio is doubtless approximately the same, since the machinery and equipment required to supply 45 productive mines, with a monthly output of 2,000,000 tons, forms a considerable proportion of the total imports. In the current issue of the 'South African Mining and Engineering Journal', Mr. Francis Harrison, in discussing the matter from the standpoint of the mining industry, points out three factors that he says have militated against more extensive business with Great Britain. These are "the difficulty of getting supplies from manufacturers, high prices, and aggressive American competition". We presume that each of these factors must apply to separate groups of commodities; they certainly could not apply consistently to the same articles, unless perhaps the prices were only relatively high as compared with those quoted by Americans. In that event the last two would merge into one. The British manufacturer prides himself on "accurate and reliable British quality" as opposed to the "American style of cheap mass product". Statistics show that \$935,000 worth of rubber belts, principally for use in the gold mills, were exported from the United States to South Africa during 1919. This is only one item, but it indicates the importance of the South African market to the manufacturer in the United States, and particularly to the manufacturer of equipment for the mining industry. It also indicates that 'cheap mass production' may not be so bad after all. The engineer who is operating the mines on the Rand selects the belt that will give him the largest return for the money spent; he takes everything into consideration, the capital invested, the cost of current maintenance, and the length of life. Apparently a great many managers have discovered that the American-made belt is the best, their yardstick is net profit, the raw material from which dividends are made; for their ultimate object is dividends. Belting is one of a hundred things that are purchased; the Rand is one of a score of mining

districts that afford a market. As a matter of fact, the field is open and in the long run the country and the company with the best product gets the business. The American manufacturer owes it to himself to make his goods known abroad. Fortuitous circumstances frequently did this for him during the War; now he must do it through his own effort.

OUR curiosity is aroused by a small pamphlet that is being distributed by the United States Steel Corporation apropos of the recent report of the Interchurch World Movement on the steel strike of September 1919. If two short introductory letters, one to, and the other from, Mr. E. H. Gary, were disregarded; if sundry allusions to biblical episodes were deleted; and if the possessive pronoun "our" before "Interchurch Commission" were changed to 'the' in a number of places, we would conclude without hesitation that the pamphlet was prepared by an attorney for the Steel Corporation; perhaps by one of the younger men, less austere and more imaginative in his style of writing than his seniors. It is a caustic, *ex parte*, frequently inconsistent, condemnation of the report of the Interchurch Commission, and a palpably biased defence of the policy and attitude of the Corporation, with a generous sprinkling of encomium for Judge Gary himself. For example: "The best way is to humanize the finance committee as it has been done with remarkable success in the personality of its chairman, Mr. Gary". Even he might blush at this fragrant compliment. The controversy between the American Federation of Labor and the Steel Corporation has two sides; much can be said in defence of Mr. Gary and his policy with respect to labor; the Corporation is doing a great deal toward the betterment of working conditions among its employees; and it is justified in publishing and distributing literature aimed to apprise the public of these things. Such is the obvious purpose of this pamphlet, which would be in no way remarkable except for what is revealed in the letters of introduction. The arraignment, it appears, is an address delivered before a meeting of Boston ministers at Pilgrim Hall by the Reverend E. Victor Bigelow of South Church at Andover, Massachusetts. In the first letter Mr. Gary expresses appreciation and gratitude that an "entire stranger" should take the trouble to present the "Interchurch world report in its true light" and asks permission to print and circulate the address. In the second letter the Reverend Mr. Bigelow reciprocates the appreciation and accedes with alacrity to the request. Were it not for the unimpeachable character of the reverend gentleman's position we should suspect collusion, of the kind vulgarly known as a 'frame up'. We venture to suggest to Mr. Bigelow that his address would have been far more convincing if he had been able to see some of the arguments on the other side; but the most astonishing thing is that the astute Mr. Gary should be misled into thinking that the camouflage of Mr. Bigelow's clerical habiliments would make the propaganda more effective.

The Position of Silver

Revival of mining in Mexico has been checked temporarily by the drop in the price of foreign silver, despite the stabilizing effect of purchases of American silver under the Pittman Act. The metal is produced most cheaply in the Pachuca district, where the cost is slightly under 60 cents per ounce; in other parts of Mexico the cost of production at the smaller mines is about 80 cents, the general average being about 70 cents per ounce. In the United States the cost ranges between 40 and 80 cents, excluding the by-product silver incidental to exploitation of ores valuable chiefly for the base metals, copper, lead, and zinc. At Cobalt, in Canada, the average cost is about 50 cents, with a low figure of 37 cents for the Nipissing mine. It is obvious that if the market price remains near 60 cents, it will be necessary for many, if not most, of the silver mines outside the United States to cease operations. That, of course, will tend at once to correct the sag in price by increasing the demand, which has fallen off for two principal reasons, of which the chief is the temporary cessation of buying from China. During the War the prosperity of the Chinese caused them to buy silver freely, such buying being further stimulated by the fact that Great Britain and others among the Allies stripped China bare of silver in order to adjust their balances in the Far East. We know how the employment of Indian troops in Mesopotamia and Egypt, and of Chinese in France, called for a large supply of silver coinage. These various abnormal conditions opened a voracious market for silver in the Orient. In Europe likewise the payment of soldiers made a call on silver coins of every kind. Since the Great War the depreciation of paper money has been so great that it has been profitable to melt silver and exchange it at a large premium for paper currency. A final blow at the weakening market was delivered by the French government when recently it decided to sell 40,000,000 ounces of silver at the rate of 400,000 ounces per week, in order to meet pressing financial demands. General conditions, as will be seen, have been extremely unfavorable to the maintenance of what the miner would consider a fair price for his product. The purchases under the Pittman Act have checked the collapse somewhat. Under that Act our Government is buying back from the American miner the 207 million ounces that it released from the Treasury three years ago for the benefit of British finance in the East. Thus far only about 30 million ounces have been purchased by the Government, and it is estimated that it will take at least four years to complete the transactions authorized under the Act, provided that foreign silver sells for less than a dollar per ounce, for if it goes above that price on the open market the American miner will cease to sell his product to his Government, and thus prolong the completion of the purchases legalized under the Pittman Act. Meanwhile the silver being produced in Mexico is being coined rapidly, thereby helping to cure the inflation of the currency caused by 'infalsifiable' paper of various kinds and denominations. The coinage of Mexican silver is proceed-

ing at the rate of 24 million ounces per annum, equivalent to about a third of the normal production. This will be a factor in restoring economic conditions in that country. Our miners are still the beneficiaries of the Pittman Act. Conditions are bad, but they might be much worse. Before they do become worse, it is likely that the decrease of production, in Canada and elsewhere, partly incidental to the curtailment of copper mining, will tend to correct the present unfavorable status of silver.

The Broad Lode Hypothesis

Our contemporary in New York has been discussing the limestone-lode theory as the chief point of contention in the Bingham suit, thereby eliciting a protest from a gentleman prominent in mining litigation. The controversy is an old one, for it may be said to have been the crux of the celebrated Eureka-Richmond suit, which was litigated in 1877. The question arose whether the 'lode' at Eureka, Nevada, was the limestone formation in which ore had been found or whether it was the system of ore-bodies more or less connected by fractures along which ore was distributed irregularly. One side wanted the entire stratum of limestone to be regarded as a 'lode' formed by the enrichment of the rock through fracturing and impregnation with minerals containing lead and silver; the other side insisted that only the connected fractures, with their local enlargements into chambered masses of ore, constituted a 'lode' or 'vein' as recognized by legal statute. At Eureka the limestone lies between quartzite and shale; it varies in thickness from a mere seam to a bed 500 to 800 feet wide, thereby forming a wedge-shaped mass of rock, in which orebodies of irregular shape were discovered. Mr. Justice Field, who delivered the opinion in the case, said that "the limestone zone in Ruby Hill, in Eureka district, lying between the quartzite and the shale, constitutes, within the meaning of the acts of Congress, one lode of rock bearing metal". The phraseology is curious, he did not say 'metal-bearing rock', as he might well have done. His main argument was that "the broken, crushed, and fissured condition of the limestone gave it a specific individual character by which it could be identified and separated from all other limestone in the vicinity. In the zone of limestone numerous caves or chambers were found, further distinguishing it from the neighboring rock". The editor of our contemporary in New York, Mr. J. E. Spurr, is a distinguished geologist with wide experience in the field, and is therefore thoroughly competent to discuss the question in a useful way. He objects to the definition brought forward in the Bingham case, namely, that "a lode or vein is mineralized rock or rocks which contain such indications of valuable minerals as to justify development with the expectation of finding ore. As soon as quartzite over a considerable distance becomes mineralized, then it becomes a lode". We agree with Mr. Spurr that this definition is so inclusive as to be unreasonable, and we would even say that it was ridiculous if it had not been the cause of a long and expensive litigation in the course of which honorable scientific men

have given testimony in support of it as a serious interpretation of geologic structure in terms of industry. At the time of the Eureka suit the structural relations of ore deposits were but little understood; in those days the simple fissure-vein, viewed as a tabular body of ore along a steeply inclined fracture in the crust of the earth, was the type upon which the law of the apex was predicated; since then the world-wide expansion of mining has disclosed divagations from this type so marked and so varied as to compel a complete departure from those early and elementary ideas of lode-structure. The classification of ore deposits has become as complex as the forms in which ore has been found in nature. It is true, the word 'lode' means something that leads the miner and in the term 'deep lead' we have its etymology disclosed; so also the word 'vein' suggests the ramification of blood-vessels in the human body. Thus 'vein' is more suggestive of definite form than 'lode', but whichever term be used it must be tied to the economic factor in mining, that is, the winning of ore, which, in turn, entails a recognition of 'ore' as metal-bearing rock that can be exploited at a profit at a given time and place. The loose description invoked at Bingham corresponds with what the Cornishman calls "symptoms of indications", it bears no relation to the shape or form of an ore deposit—and that, it will be argued, is no defect, for are not some ore deposits without visible boundaries, their limits being dependent upon the valuable metallic contents of the rock as determined by assay, the delimiting quality of which depends upon the current value of the metal being sought and the cost of the operations needed to extract it in marketable form? On the other hand, the idea that the presence of metal in proportion however minute suffices to turn a rock formation into a lode is untenable, for then the ocean is a lode and the peninsula of Lower California is another. The *reductio ad absurdum* is easy, as Mr. Spurr shows in his humorous reference to the geology of Bingham. The clue to the difficulty, of course, is in the recognition of the real meaning of 'ore'. If "the quartzite over a considerable distance becomes mineralized", it does not become a 'lode' unless the mineralization is synonymous with ore; in other words, the mineralization must have been so intense as to result in a concentration of economic value, that is, one yielding a profit to the miner. Besides this economic factor, of exploitability, there is implicit in the words 'lode' and 'vein' the old idea of structure. The enriched rock has boundaries; even if they have to be determined by assay, they will be found to be tied in some way to structural lines or planes, to walls, to fractures, to shear-zones, to something identifiable with the mode of origin of the ore deposit. At Bingham, for example, even the geologic sections submitted by the advocates of a limestone lode indicate some genetic connection between the impregnations of ore and the faults, fissures, and dikes that traverse the terrain. The Court held that the limestone was not continuously mineralized, that the part intervening between groups of mine workings was "unmineralized and barren", emphasis being

placed on the fact that this part of the formation had not been prospected. Here comes the suggestion for a distinction between the geologist's idea of what constitutes minable ground as against the miner's idea of ground that he ought to prospect; the miner's object is to make money, the geologist's is to obtain scientific information. If the geologist had to spend his own money and apply his own muscle, he would, we think, restrict his definition of 'lode', from whole rock formations containing traces of metal to those recognizable channels and delimitable zones along which the agencies of mineralization have so concentrated their physical forces and chemical reactions as to produce enrichments sufficiently valuable to incite the miner's toil, not merely excite the geologist's curiosity.

Mr. Bain's Appointment

On the last day of 1920 it was announced from Washington that Mr. F. G. Cottrell had resigned as Director of the U. S. Bureau of Mines and that his successor would be Mr. H. Foster Bain. Dr. Cottrell's public spirit is so well known as almost to be proverbial; his scientific discernment is likewise recognized cordially by his fellow-workers. He was Assistant Director of the Bureau when last year he succeeded Mr. Van H. Manning as Director and previously he had been chief metallurgist to the Bureau. Mr. Manning, it will be recalled, was assistant to the late Joseph A. Holmes, who was the first Director, taking charge at the time, in 1910, when the Bureau was created by enactment of Congress. Dr. Cottrell has been chairman of a division of the National Research Council, this being the kind of work most congenial to him. He will return to it now. The responsibilities that he has carried most capably for the past year are transferred to Mr. Bain. As to Mr. Bain, he needs no introduction to our readers. He was editor of the *Mining and Scientific Press* from 1909 to 1915, and then for a short time he was editor of 'The Mining Magazine' in London before going to China in 1916. From there he was called in 1917 to become assistant to Mr. Manning, so he is already familiar with the work that he will now direct as chief. In 1918 he resigned to return to China, where he was engaged in the examination of mines for an important Anglo-American syndicate. He returned to this county in November. By that time he had been invited to succeed Dr. Cottrell and after some hesitancy he accepted the appointment, being urged to do so by many of his friends. He is 48 years of age, a native of Indiana, a Ph.D. of Chicago University and a post-graduate student of Johns Hopkins. He has practised as a mining engineer in several States and has traveled in many countries; for four years he served as State Geologist of Illinois. He has lectured on economic geology at several universities. This outline of his career indicates an ideal preparation for the important task to which he has now put his hand. By temperament, experience, and personal qualities he is peculiarly fitted to be an officer of the Federal government. We wish him the success that we feel sure he will deserve.

DISCUSSION

Silver as Money

The Editor:

Sir—I am just in receipt of your issue of this date in which Mr. Blamey Stevens has for discussion an article entitled 'An International Association of Silver Producers'. Having been very much interested in silver for the past ten years I have had occasion to make some study of the metal and its "peculiar position" among metals. Just in the last issue of the 'Engineering and Mining Journal', Mr. Spurr publishes an article by myself under the title of 'An Advocate of Bimetallism', which was more of an argument against the Gold Bonus Bill now under consideration by Congress.

Now, if you will be kind enough to allow me the space in your worthy journal, I would like to answer Mr. Stevens with this letter, under the title of 'Silver as Money'.

In July, Mr. Charles Butters came through Nogales and delivered an address on silver, with the same object in view as Mr. Stevens. Today he is back in Nogales after an extended trip in the East, where he informs me that he got the "cold shoulder" on such an idea everywhere he went. He seems to have become discouraged, and has closed down some of his silver mines. Now Mr. Butters, in my opinion, made the subject look like too much of a personal matter, but, on the other hand, always emphasized the fact that silver was necessary as money.

I am surprised that any man should attempt to organize an association to sell a certain commodity to a government and start out, like Mr. Stevens, by saying that it was "no longer suitable" for the purpose for which said governments would use it. It will be my object herewith to state facts pertaining to the issue from which any reader can arrive at his own conclusions.

In his recent address before the Federated American Engineering Societies, Mr. Herbert Hoover, its president, among many good things, said: "This engineering association stands somewhat apart among these economic groups in that it has no special economic interest for its members. Its only interest, in the creation of a great national association, is *public service*. . . And if engineers, with their training in quantitative thought, with their intimate experience in industrial life, can be of service in bringing about co-operation between these great economic groups of special interests, they will have performed an extraordinary service".

I believe the proper way to approach the subject of silver as money is first to go to the fundamental principles

upon which its value depends. So, first let us look up a bit of history on the subject. Shekels, or pieces of silver, are referred to in the Book of Genesis. Abraham, in the land of Canaan, bought a field for sepulture and paid for it in silver. Silver as well as gold was employed in the erection of Solomon's temple at Jerusalem. In 1000 B.C. the ratio of silver to gold was 12:1. At the Christian era it was 9:1. At 500 A.D., just 24 years after the downfall of the western Empire of Rome, the ratio was 18:1, but in 1100 A.D. it had fallen to 8:1. At the close of the seventeenth century it was 10:1, and at the end of the last century it was 15:1. In 1850 the ratio was 15.4:1. In 1873 it was 16:1. In 1896 it was 30:1. In 1902 it was 39.15:1. In 1913 it was 34.19:1. During the War, and just after, it varied from almost 50:1 to 15:1.

I presume it is owing to these last few years of extraordinary fluctuations that Mr. Stevens draws his conclusions that silver is no longer "suitable for money". I agree with him that such wide differences are uncalled for, even in the worst of times, and that something should be done for silver. However, we must not lose sight of the fact that such regulations as favor a minority interest in this line or any other line will neither be popular nor stand the test of time.

This is an international subject, I well appreciate, and it must be handled as such. But I feel sure I am absolutely correct in saying that anything done to control the price of silver and thus eliminate speculation must from the nature of the case come from the other side, that is, the consumers and governments in this case.

In this age of civilization we all constitute the government of our individual nations and we must be made to see the absolute need of the things that our tax-money is to buy; and, furthermore, the great struggle through which the world has just passed certainly has shown the absolute need for co-operation among nations and the need of an international congress, which unquestionably will soon be adjusted or formed with all nations participating.

Hence all that is wanting in the case of silver is to prove that it is necessary to the united governments, then the correct price and demand will take care of itself. And this proof I hope to give in the following paragraphs.

Money is merely a medium of exchange. And although there are a few who do not even think that we need a medium of exchange, I believe it will stand without further argument that to carry on trade and commerce some medium of exchange is absolutely essential. Now, does this medium of exchange have to have an intrinsic

value? That is the question before the world today. If it does not, why produce gold? Why mine more silver? I say, cut them both out and continue to issue paper (as it is about the cheapest thing we can find). Some say, use a bushel of wheat for a dollar; all right, everybody will do nothing but plant wheat, while others will charge more than it is worth for transporting it. Name anything else that would be suitable for money, analyze it, ask if it can be counterfeited, preserved, etc., and see to what it leads.

Silver and gold possess the physical and chemical characteristics necessary for a permanent international medium of exchange. Gold today is at a premium in Europe. Why? Because it is scarce, and therefore has value. Some American mining-men and bankers are advocating a \$10 per ounce bonus on American gold. This law should not pass, because it favors the few gold miners, and will tend to disturb the only standard we have. The gold miners are now being favored by the decrease in the cost of production. The American silver miner sold, through his Government, under the Pittman Act, practically four years' production in advance for the just price of \$1 per ounce. France as a last resort melted up her silver coins and dumped them on the market further to decrease the price of silver. England, we read, for the first time in history has been able to pass paper money in India, and still she produces 75% of the world's gold, with which she expects to pay off her international debts. Now, with all of these basic facts before us, how can we argue that a medium of exchange does not have to be backed up with something of intrinsic value? However, for argument's sake let us assume the contrary.

In modern times what has been this medium of exchange? Letters of credit, bills of exchange, paper money, bonds, notes, checks, and drafts, etc., all of which are good, convenient, necessary, and desirable by business men. I do not argue for a system that would abolish these, but I do say the world of nations does need something to fall back on in case of war, and this, as argument and history show, must be gold and silver. I say, encourage all the gold and silver production possible, encourage its use in the arts, as small money, in jewelry, ornaments, table-ware, moving-picture films, photography, and every other use possible. The production of gold and silver, I think, can never exceed the demand, if they are fixed in price at some definite ratio—weight for weight—of pure metal. By so doing, in case of an emergency, when foreign exchange on paper falls in value, there would be some stocks of so-called luxuries to fall back on and put into use as money. The best example of such action was shown by Germany during the War in the case of copper, the melting up of church-bells and copper utensils of all sorts. I further believe that if the world had been on a better and sounder financial system prices during the War would never have risen to such a high level, and in turn the different nations would not have been allowed to extend such unlimited credit, the results of which we now face in a period of depression. Why?

Foremost because Europe has not the money with which to buy our products, that is, she has a money, but we say the exchange is from 5 to 75% of what they value it in trading among themselves. Can it be expected, for example, in the case of France, whose franc is quoted at about six cents, to buy our copper even at 14c. and pay the exchange, which would be about the same as paying us over 50c. per pound for copper. It is not quite that bad with some other nations and even worse with others at the present time. This example applies to practically every commodity that we produce. It seems to be the direct result of the system of trading on an indefinite credit basis. Now if foreign exchange is going to paralyze business, and cause hunger and suffering the world over, as well as undue fluctuations in all commodity prices both up and down, it certainly seems to prove that it is essential that the medium of exchange shall have an intrinsic value, either directly or indirectly.

We learn that our warehouses are full of food, wool, cotton, and other raw materials. Our wheat districts have no place to store more flour. Our mines are having to curtail production. There is no market for our products. On the other hand, we are asked to feed starving nations in Asia, and in China people are starving by the millions. Ample supply on this side and a pressing demand on the other. Why do not the laws of supply and demand function? Many thought the political elections were the cause, others still think that after the change is effected at Washington, things will be better; however, they will find that other things, more important, are responsible for present conditions. The fault is simple and may be expressed in a few words: an unstable medium of exchange. The making of a commodity out of silver, and even gold. All of which should be stable and used as definite measures only.

Now, what is the remedy? Either, further unlimited credits, or else call a special International Monetary Conference, sending authorized representatives from all nations, and first adopt a definite ratio between gold and silver with a definite proportion of credit expansion that would govern all nations alike, so that the different nations would ultimately adjust their coinage to that ratio, and the gold and silver money would become eventually international currency. To avoid the expense of transportation, the nations should issue gold and silver certificates indicating on them the actual weight of pure metals deposited in their own vaults. Thereby a lot of silver would be brought back into monetary use that is being held as a luxury now in the European countries, and in that way the more wealthy nations could extend further credit to such needy nations as their credit expansion warranted, and business would commence immediately. As silver and gold become more plentiful the national debts of the different nations could be paid or decreased, and the ratio of credit expansion, with gold and silver stocks as a basis, might be all that would have to be altered in future generations. Of course, the details of ratio, seigniorage, credits, etc., would have to be worked out from statistics, but they present a minor de-

tail. All of which could be done in half the time that Congress might spend in debating the McFadden Bill.

I believe it is time that we Americans quit wasting time on dreams and get down to business. Unlimited credit means waste, extravagance, speculation, and sorrow. Cash, with limited credits and conservatism mean prosperity, economy, and happiness. We producers of metals and agricultural products must realize that war prices were a nightmare. On the other hand, consumers must realize that progress means better living conditions, higher esthetic wants of individuals, consequently higher wages and production costs.

HUGO W. MILLER.

Nogales, Arizona, December 18, 1920.

Power From Low-Grade Fuels

The Editor:

Sir—Referring to my two previous letters on this subject, I find in Bulletin 55 (1913) of the U. S. Bureau of Mines, by R. H. Fernald, that in that year there were from 900 to 1000 plants in the United States generating a total of 200,000 hp. from producer-gas. Of a list of 722 plants, 610 were using anthracite, 77 bituminous coal, 32 lignite, 1 wood, and 2 oil. A map accompanying this publication showed that most of these plants are in a region covering the north-central and north-eastern States. In the South and West, the installations could be counted on two hands, showing that where oil is produced and plentiful, it is either burned under boilers or the distillates are used in stationary engines. The advent of the oil-engine, its general simplicity, and an abundance of oil stopped development of the gas-producer; but as liquid fuel becomes scarcer and higher in price, the use of producer-gas may be extended. I understand, on good authority, that the net result of gas-producer installations in America has been to make a demand for special fuels, which work easily in gas-producers, so as to reduce the labor charge; in fine, they failed to utilize low-grade fuel or waste-products. How different is this result to that of British and European practice, where many times the American total of producer-gas plants are in successful operation. It might be helpful if engineers and others interested secured copies of the following Bulletins of the Bureau of Mines, which cover producer-gas power both here and abroad: No. 4, 7, 9, 13, 31, 55, and 109; also Technical Papers No. 9, 20, 123, and 207.

Prospecting

The Editor:

Sir—I read with interest an advertisement in your last issue, advising young graduates to go prospecting, and it brought to my mind certain questions.

First, like most young technical men from the East, I have had little opportunity to come into contact with the old-time prospector and I thoroughly realize that it is no game for a tenderfoot to play on a lone hand. Therefore,

I would like to know how to get in touch with some old-timer.

Second, what districts are there left to prospect, at the present time, other than Mexico?

Third, how much capital is needed, and what are the chances of getting grub-staked?

Perhaps some of your readers can enlighten me on these questions.

R. S. EVERIT.

Ray, Arizona, November 19, 1920.

Economic Interests

The Editor:

Sir—I am constrained to enlarge upon the opportunities which would present themselves to men charged with the many tasks incidental to rehabilitation and reeducation (a poor word, but mine own), opportunities that only business men would seize and that engineers would probably ignore.

There is a mill-foreman in a Central American republic who is dissatisfied with his salary. A few months ago he wrote to the New York Steel Exchange, which exports mining machinery, asking if there was any way in which he could add to his income. His letter reached the proper desk in the routine way, and the reply was designed to bring out a statement of the foreman's opportunities. It turned out that besides his immediate employers, there were other mining and industrial companies in his neighborhood, as well as a projected short railway and a village hydro-lighting plant. The foreman's general knowledge in the way of requirements of supplies, iron, corrugated iron, waste, balls, bolts, drill-steel, and the like, made it easy for him to help his neighbors prepare their formal orders, but his ignorance of selling, market prices, exporting, and credit matters is simply appalling. He is a good engineer, but any ten-year-old bank messenger knows more of financial matters.

The export house is always glad to take the trouble necessary to complete the transactions, and this mining engineer is an apt pupil. A long letter from him recently expresses wonder how he could formerly go through a mill, seeing the needs of chrome spare parts, Dorr machines, ball-mills, red-edge shovels, and similar items, and calmly ignore the opportunity to make money. He says he needs the money, too. Seems to have a wife and some children. It is clear from his letters that he formerly looked over a mine and mill from a nose-to-the-grindstone point of view. Now he is a much more useful member of society.

Of course you, Mr. Editor, realize that advance information leading to business is worth money to manufacturers and exporters and to the buyers themselves, and buying advice is worth money to our foreman's neighbors. At first he got business after hours, but soon discovered that he was losing money working for wages. Upon one occasion his enthusiastic faith in the credit of one buyer, whom the exporter would not trust, cost him \$280 on an order he personally guaranteed; but it was cheap experience.

Not a day need pass in the life of a mining engineer

abroad without his writing to New York of an opportunity to do business. Hamilton (you do not know which Hamilton I mean) would have been a millionaire by this time, had he known and remembered this, or had he married and had his wife been told of the opportunities he was missing. Patterson (the above parentheses applies to Pat also) has simply been too lazy to pick up this money. I know of only about 20 engineers who draw drafts like these on New York.

One engineer who lives in Bolivia is about the laziest (commercially) that I know, but I met his wife. She heard me scolding her husband one day about missing his opportunities. He accompanied me to a near-by property and watched the writing of a simple spare part and supply order. When we returned to his house, I showed him and his wife what would be charged to the order for overhead and traveling expenses, and explained to his wife that if he did this work, no doubt any manufacturer would send him an agent's pay-check. Well! He sends up orders, but he is my most deadly enemy. His wife leaves him not a moment's peace. Every *dia de fiesta* they visit some plant, and instead of comfortably enjoying a discussion of jigs and tables and tailings, he is allowed only half his time for this, and must spend the remainder with the buyer, the *mayordomo* and the *pulpero*. His wife has no ethical ideas so far as concerns the kind of material to be ordered, and considers groceries or *tocuyo* as ethical as ball-mills—and much more profitable. Moving-picture machines and a complete hospital equipment are some of his items, and represent as well as anything his "economic interest" in Bolivia, which Hoover says the engineer does not have.

This engineer (and his wife) have been at this for a year. He is a far better employee for his own company and now knows how to buy. Engineers do not. He makes more in his odd moments than he earns as salary and is independent of salary and job. As time passes, he is less trouble to the exporter and manufacturer because he sends his orders complete; he attends to collections; he makes it easy for the buyer, the seller, and the shipper. His wife writes most of the orders and endorses all of the agent's pay-checks.

No one in any industry, or profession, without exception, has the opportunities within the reach of the mining engineer. A near-by prospect is attractive. He can offer it to his employers. If they are not interested, he can offer it to New York. There is no limit, of course, to the number of mines that New York is willing to buy. A man with ear-rings sold a mine here recently for more gold than there is in all Germany and Austria. A live engineer cannot only send advance information on improvements and new works in mining, to exporters and manufacturers who are glad to pay for new business, but he can tell J. G. White & Co. of proposed port works and railways, Pelton of hydraulic developments, Redwood of pipe-line projects, and so on *ad infinitum*. The pages of the journals will give him a name for every different line. He will be careful in his choice of correspondents for each important item, and then will help to close the busi-

ness. No one will pay for words. The engineer is in an ideal position to guide purchases because his opinion commands and merits respect and confidence. He is head and shoulders above the ordinary salesman in the opinion of the machinery-buyer, the machinery-seller, the works-contractor, the buyer of mines, and the exploration company.

Few engineers but could widen their field of activity, broaden their experience, and thicken their bank account by seeing what should be done for and by their neighbors and telling somebody about it. These activities are only recommended to engineers who have thought of ways of using more money than their present income. It would be energy wasted for engineers who are paid a salary which supplies all their needs.

I wish this message could reach the wives of engineers abroad, and I dare each of you to read it aloud to your wife, explaining it to her patiently and carefully and showing how it applies to your particular case. The rest I leave to her, if she has any use for an additional thousand or two a year, and if it does not result in Mr. Hoover changing his opinion of the "economic interest" of mining engineers, I do not know the species 'wife of a mining engineer'.

AMIGO.

San Francisco, December 17, 1920.

Bunker Hill Smelter

Sundry corrections in the text of the article on the Bunker Hill smelter, beginning on the next page, were overlooked owing to the early date of going to press this week. On page 53, line 7, the assay of the Caledonia ore should show 0.6% copper; in line 26, "the second tuyere jackets" should be "the second-tier jackets"; in the first line of page 54, the revolutions should be 4700; in line 35 of the same page, the height of the charge column should be 11 feet; in line 7 of page 58, "two pounds" should replace "three ounces".

Most of the high-grade manganese ores in the Batesville district of Arkansas contain 45 to 52% of manganese, though some of the ore that has been shipped contained as much as 60.80% in carload lots. They generally contain from 3 to 8% of iron, 0.15 to 0.30% of phosphorus, and 2 to 8% of silica. Some of the ore that has been marketed contained more than 0.30% of phosphorus, and a very little contained 0.50% or more. As the usual requirements of ores that are used for metallurgical purposes specify that their phosphorus content should not be in excess of 0.25%, it is evident that some of the ores are too high in phosphorus. Phosphorus is, in fact, the most harmful ingredient in the ore of the district, but as it is not uniformly disseminated through the ore it can generally be avoided in mining. At some places the silica content is high, exceeding 8%, which is the maximum amount that is usually accepted by buyers without imposing penalties, but at some such places the silica content can be materially reduced by properly treating the ore.

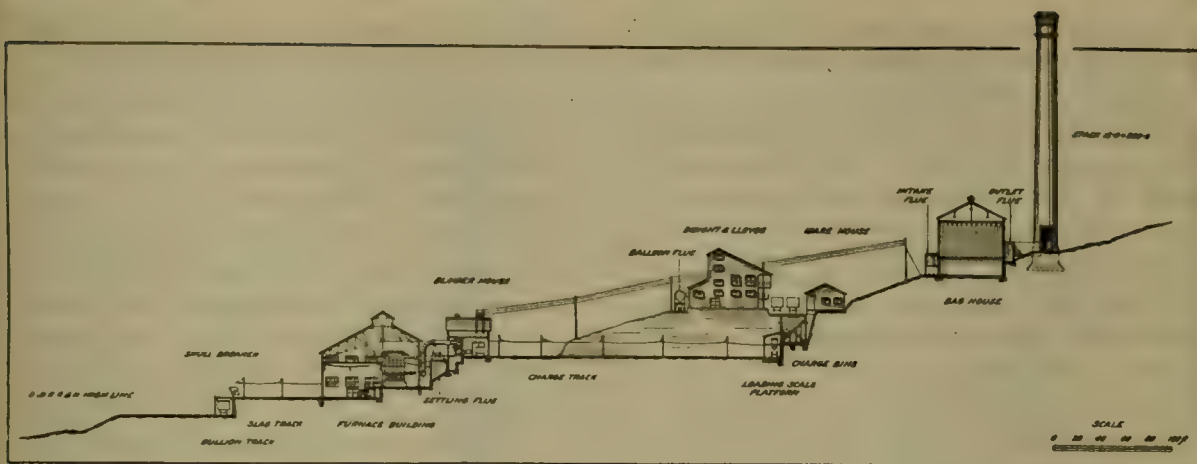

FIG. 1. CROSS-SECTION OF THE BUNKER HILL SMELTER

The Bunker Hill Smelter

By T. A. Rickard

THE SITE of the smelter is the old Bingham ranch, a tract of 80 acres adjoining the Bunker Hill mill-site on the west. It is particularly well suited to the purpose, having a draw or gully on each side of the central hummock; in the eastern hollow are the receiving-bins, the crushing-plant, and sampling-mill; in the west hollow are placed the charge-bins; on top of the ridge between these two depressions are the roasters, track-scales, warehouse, shops, bag-house, Cottrell treater, and stack. Below them are the furnace-buildings, and the refineries. The main level of the smelter has an elevation of 2400 ft. and is connected with the Bunker Hill mill-yard by a standard-gauge railroad, which is a little less than a mile long. There is also a connection on the west with the Sierra Nevada branch line of the Oregon, Washington Railroad & Navigation Company.

GENERAL ARRANGEMENT. From the top of the first ridge west of Government gulch, that is, on the side farthest from Kellogg, one obtains an excellent view of the entire plant. On the extreme right, on top of the opposite ridge, is a 125,000-gal. storage-tank for fuel-oil and behind it are the tanks that store water for the furnaces and for domestic supply. Next below comes the Cottrell treater, a tall narrow structure, and to the left of it is the stack, made of radial brick, 200 ft. high and 15 ft. in diameter inside. Against it appears the bag-house, which is built of brick and contains three compartments, each of them holding 400 woolen bags, through which the fume filters. A little in front and west of the bag-house is the fan-house, which contains two No. 19 Niagara conoidal 160,000-cu. ft. fans, for pushing the furnace gases through the bag-house and up the stack. The same building contains electrical equipment for the Cottrell treater. Athwart these buildings is seen the main flue ascending the hill. From where the flue passes

under the main railroad tracks to the Cottrell treater it is divided into two parts. The upper part is used for the roaster gases, and the lower part for the blast-furnace gases, and also for a direct connection to the stack. In the gulch immediately below the spectator are the charge-bins and railroad tracks. On the sky-line, and below the bag-house, is the assay-office belonging to the Hecla, where a representative of that company is domiciled. To the left, below this assay-office, is the roaster-building. In front of it is a steel balloon-flue leading to a chamber that serves for humidifying the gases before they enter the main brick flue. Below the roaster-building is a small change-house for the employees; then comes the charge-track leading to the blast-furnaces; the first building below this track is the power-house, which contains the blowers, compressors, and motor-generator sets, and also the switchboards that control the distribution of power to the different parts of the smelter and refinery. Next is the furnace-building, and in front, just below, is the lead refinery, athwart which appears the silver refinery. On the extreme left is a building containing the Bonnot coal-pulverizing plant. At the rear of the roaster-building one can get a glimpse of the top of the crushing and sampling buildings in the gulch beyond. To the right of the silver refinery there is a 100,000-gal. tank that is used for cooling the jacket-water from the blast-furnaces, refining-furnaces, lead-casting wheel, etc., and in the gulch at the spectator's feet is the building in which copper sulphate is made. The system of railroad tracks includes the high line, on which come the ore, coke, and flux. Below the lead refinery is another track for the removal of the product. The silver bullion is shipped by express on a passenger train, at the station named Bradley, after the president of the company. The main office, assay-office, warehouse, and machine-shop are not visible from

our point of vantage, being hidden by the other buildings. A reference to the plan and section (Fig. 1 and 2) will make the description clear.

After preliminary surveys, the construction of the plant was started on May 1, 1916, and the first blast-furnace was blown in on July 5, 1917. The plant cost \$2,500,000. The accompanying photographs show three successive stages of the construction. The plant was designed by Jules Labarthe, of the firm of Bradley, Bruff & Labarthe, of San Francisco.* It consists essentially of the crushing and sampling mill, Dwight & Lloyd sintering machines, Traylor blast-furnaces, lead refinery, silver refinery, besides bag-house, Cottrell treater, power-station, and the necessary equipment for receiving and storing the various materials that go into the furnaces.

THE SAMPLING-MILL consists of two parts, for coarse and fine crushing respectively. The former has three receiving-bins, and the latter four. These bins are built of wood, and each has a capacity of 3500 cu. ft. Material of large size goes through the coarse-crushing plant, which contains an 18 by 30-in. Allis-Chalmers jaw-crusher. This building has the necessary elevators and screens, so that in crushing limestone the oversize material, about 2½ in., is delivered back into a railroad car and can be taken directly to the blast-furnace charge-bins and stock-pile, while the undersize can be delivered directly to one of the roaster-charge bins. If it be necessary to crush the material fine, it can be passed to the fine-crushing plant, which has the following equipment: one 48-in. Symons disc-crusher, two 16 by 42-in. Allis-Chalmers rolls, and a Mitchell vibrating screen, with the necessary elevators and belt-conveyors. There is a 30-in. belt-conveyor in front of the three bins of the coarse-crushing plant; this conveyor feeds directly into the jaw-crusher. A similar conveyor serves the four bins of the fine-crushing plant, and feeds directly into the Symons disc machine. At the discharge end of the fine-ore belt-conveyor, and directly above the receiving-hopper of the Symons machine, is placed a 220-volt magnet, made by the Electric Controller & Manufacturing Co. This magnet, Fig. 3, removes steel, scrap-iron, nails, etc., that may have accompanied the ore into the Symons machine. Such pieces of scrap might otherwise get into the disc and cause an expensive shut-down. There is very little trouble with the Symons disc-crusher, because the feeding-belt is also used as a picking-belt and when lead matte is being crushed any pieces of lead that may be in the matte can be easily seen and picked out, the matte having been already through the coarse-crushing plant. I noticed a collection of material that was caught by the magnet; it consisted of tobacco-cans, snuff-boxes, railroad spikes, bolts, fish-plates, nails, hammer-heads, and pieces of drill-steel. The 'bit' of a miner's drill is non-magnetic, and such material has to be picked by hand off the

feeding-belt. An ingenious feeder is used at this point. This is set directly under the bin and over the belt. The gate of the bin is opened wide and the feeder is controlled by means of an electric switch, by which the operator can regulate his feed to suit the Symons disc. On the Mitchell screen, it is customary to use Ludlow-Saylor's wire-screen No. 523, and also No. 581. There are three Vezin sampling-machines, which take the entire stream of crushed ore during part of the time, and there is also a small set of Chalmers & Williams rolls, 12 by 12 in., immediately above the last sampler. The cut from this last sampler is caught in a small cart that is pushed by hand into a room where the sample is cut down on a floor covered with steel plates. One sample is taken to the assay-office, while the reject is put in a sack and kept in reserve in case re-sampling should be required. The ore is taken from the mill by a 20-in. belt-conveyor dis-

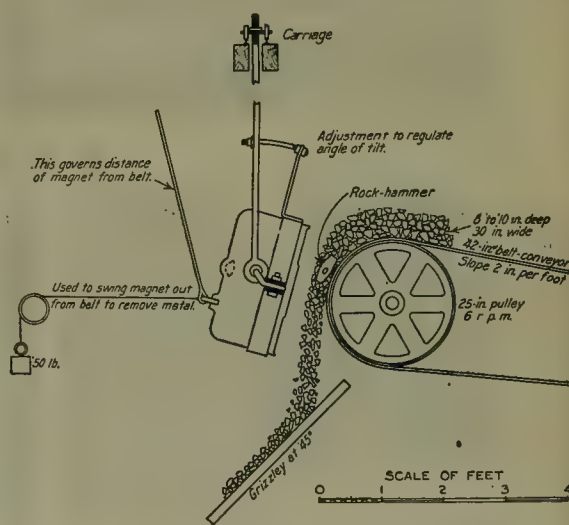

FIG. 3

charging by means of a tripper into one of the series of eight roaster-charge bins. At the end of this belt-conveyor there is also an inclined belt-conveyor of the same size, so that if it becomes necessary to store the material, or take it to the furnace-charge bins, it can be fed directly into railroad cars. There is another row of bins immediately south of those just mentioned. The tripper cannot reach these bins, so that when it is necessary to fill them with ore from the sampling-mill, it is simply transferred in railroad cars. However, this second row of bins is generally used for material that can be hand-sampled directly out of railroad cars. There are three lines of track over this system of bins and they are so arranged that a car can be spotted on the central track and unloaded into bins on either side.

THE ROASTING-PLANT consists of nine Dwight & Lloyd sintering machines and one Wedge furnace. This last has seven hearths, each of 23-ft. diam.; but it is not in use at present. The Wedge furnace was used for roasting the lead matte, but for over a year the matte has been double-roasted on the D. & L. machines. At the present time the

*Mr. Easton, the manager, tells me that particular credit is due to Walter K. Mallette in directing the construction of the smelter. Thanks to his energy and good judgment it was possible to complete the erection of the plant, without delay or confusion and at a minimum of expense, within a little more than one year.

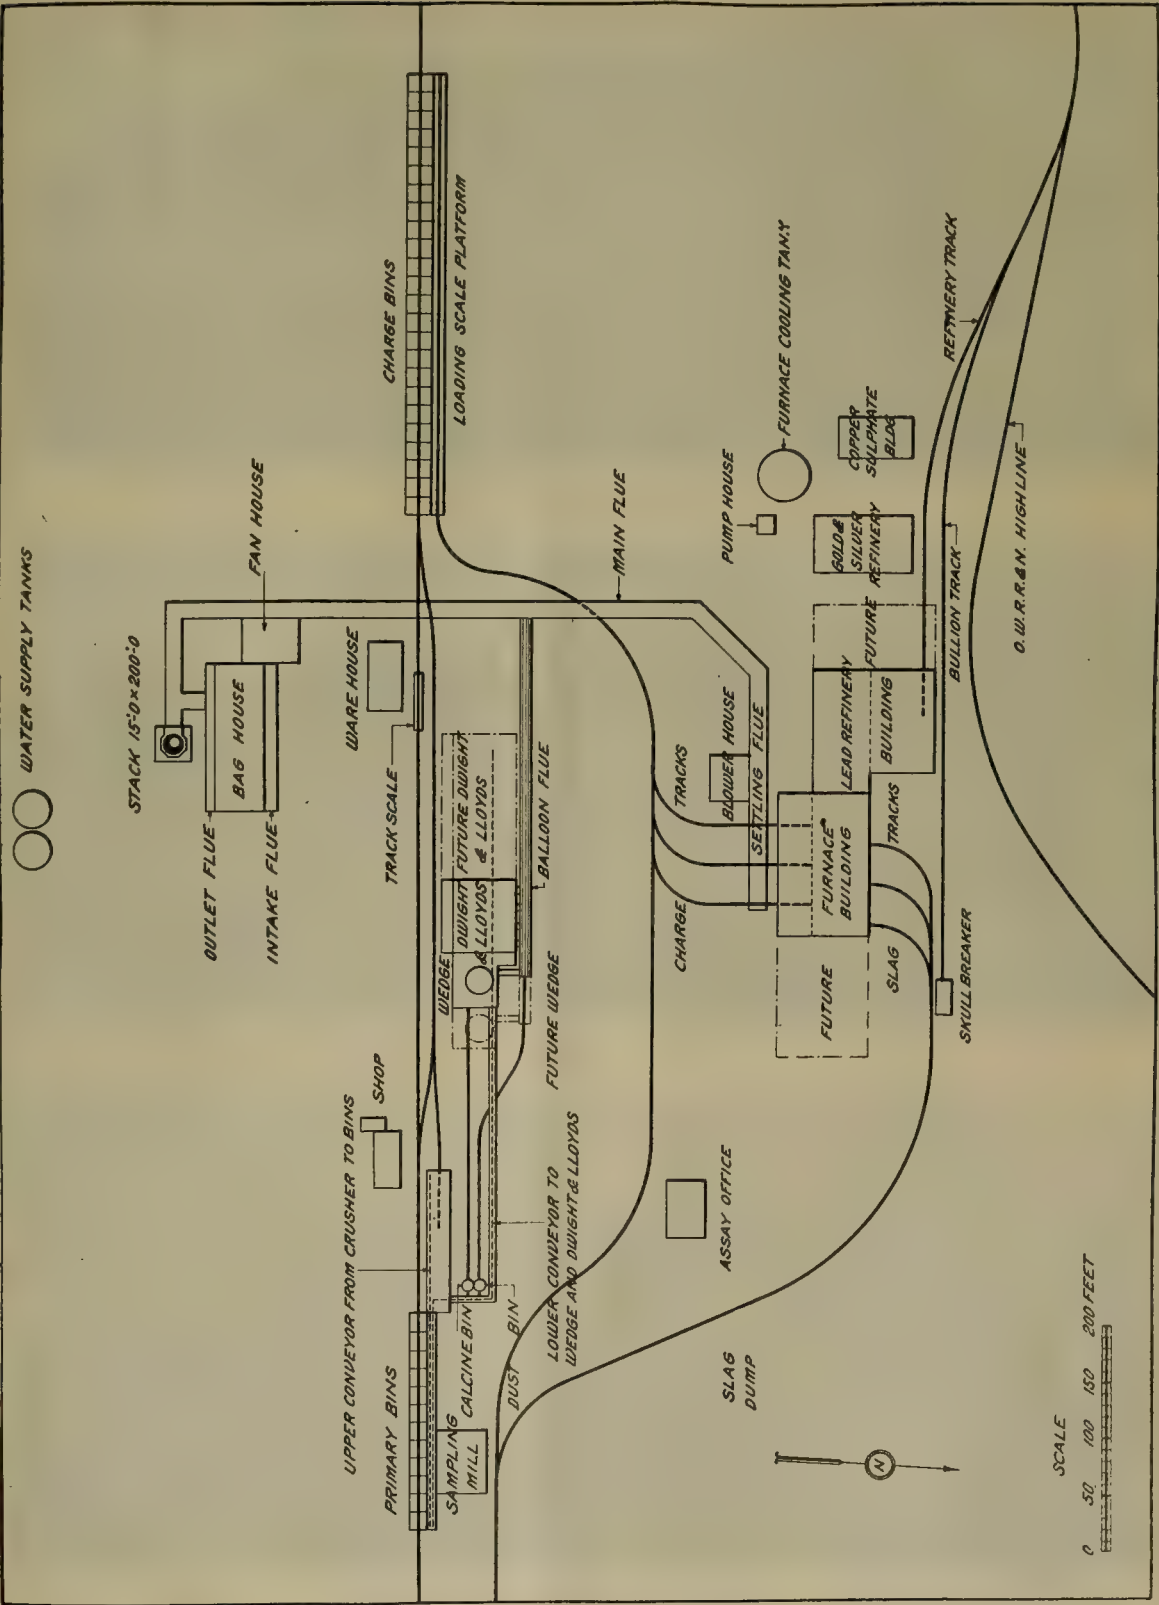

FIG. 2. PLAN OF THE BUNKER HILL SMELTER

FIG. 4

smelter is receiving no material that has a sulphur content high enough to need preliminary roasting in the Wedge before treatment in the sintering machines. The charge is brought from the different bins by a series of 20-in. belt-conveyors to the receiving-hoppers of the D. & L. machines. At the top of the building there is a tripper that can be set over the hopper of any machine. The charge is fed from the storage-hopper of each roaster by a belt-conveyor into a blind-trommel mixer and it is then delivered onto the D. & L. grates by a swinging-spout feeder, as shown in Fig. 4.

The grates used on the D. & L. machines were designed at Trail, by R. H. Stewart, formerly general manager for

the Consolidated Mining & Smelting Company of Canada. His 'pallet', one unit of a jointed moving hearth, has five interlocking serrated grates; so that the interior grates are fixed and loose alternately, causing the sintered ore to detach itself readily when about to be dumped. A new method of fastening the grates to the pallet has been devised by A. L. Larson, mechanical superintendent in this smelter, and a sketch of it was given to me by M. H. Sullivan (McGill '04), the superintendent* of the smelter. See Fig. 5. There are only three bolts holding the fish-plates to the sides of the pallet where in the original grate there were seven bolts. This new method of attachment simplifies the replacement of a broken grate. Each grate has three loose members, and on account of their differential movements it is kept clean. Sidney Butler, the general foreman of the roasters and blast-furnaces, has devised a method for leveling the movable members of the grates. This device as developed here consists of a heavy cast-iron wheel—a discarded crane-wheel is suitable—mounted on a

*To whom I am indebted for invaluable assistance in the preparation of this article.

FIG. 5. DEVICE FOR CONNECTING THE GRATE TO THE PALLET OF THE DWIGHT & LLOYD SINTERING MACHINE

ON AUGUST 20, 1916

THE BUILDING OF THE SMELTER

shaft that is held in place by two pieces of angle-iron bolted to the frame of the machine. Each angle-iron is attached by a single bolt. This allows the wheel to move up and down, and when the pallet passes under the wheel, the movable members are leveled to the plane of the fixed members. If the grates are not leveled, there is a tendency for the sinter to stick to the projections of the tilted members at the discharge end of the roaster.

At the present time pulverized coal is being used for the ignition of the sulphur in the ore to be sintered, whereas formerly fuel-oil was used, and the brick muffle has been replaced by one of cast-iron. The first cast-iron muffle was made of individual blocks that were simply dropped into the old brick muffle-frame. A strip of $\frac{3}{8}$ by 2-in. iron is riveted on the inside of the frame, the lugs of the cast-iron blocks resting on top of these strips. It was found later that the muffle was equally satisfactory when made in larger sections, as shown in Fig. 6. These cast-iron muffles proved to be much cheaper than those made of brick, and a repair can be made in a few minutes, because it is not necessary to change the muffles. Each sintering machine is served by a fan having a capacity of 10,000 cu. ft. of air per minute, and the fan is driven by a 50-hp. motor. Extra dust-boxes were added between the machines and the fan so that any fine material that would be pulled through by the suction can be separated. These boxes catch the fine material so that it settles before it has a chance to cut the fan-blades, thus prolonging the life of the fans considerably. Under the sintering machines runs a belt-conveyor that catches any spill and removes it to an elevator, which carries it back to the feed-belt at the top of the building.

Two types of muffles for pulverized coal are shown in Fig. 6. The coal is fed to the roasters by a 41-in. diam. fan, with six $\frac{1}{2}$ -in. blades making 1200 r.p.m. The feed-pipe is nine inches in diameter; this is cut down to five inches for the return line. Directly over each machine there is a valve for feeding the coal to the muffle. There is also an auxiliary pipe-line to supply the extra air that is required to burn the coal. The coal-muffle is simple in construction and seems to work satisfactorily.

Three of the D. & L. machines are used for pre-roasting material such as lead matte, fine table-concentrate, flotation concentrate that can be moved on belt-conveyors, and any other fine or coarse material with a sulphur content too high to be eliminated successfully in one roasting operation.

The sintered material, or 'roast', discharges into standard-gauge railroad cars of 110,000-lb. capacity. The pre-roast material (partly sintered and its sulphur content reduced to 6 or 7%) is weighed and taken back to the sampling-mill for re-crushing, whereas the 'roast' (completely sintered and its sulphur reduced to less than 3%) is weighed and dumped directly into the blast-furnace bins. The bins at the sampling-mill that are used for the first-roast or pre-roast material are lined with 'gunite' three inches thick on the sides and four inches thick on the bottom. This gunite, a mixture of cement and sand, is shot by a 'cement gun' upon the sur-

face to be coated; it is reinforced by $\frac{1}{2}$ -in. rods and by a No. 8 wire-screen of triangular mesh. Spikes are driven into the sides of the bin and the reinforcement is hung from these spikes. The spikes, of course, also help to reinforce. Since the bins were lined with gunite, no more trouble has been experienced from the hot 'roast' setting fire to the wood. The bins are also fire-proofed on the outside by a layer of gunite about $\frac{1}{4}$ or $\frac{1}{2}$ in. thick reinforced with chicken-wire. This serves to preserve the wood from decay.

The fume and gas from the roasters pass to the Cottrell treater through a 9-ft. balloon flue, which connects with a spray-chamber and then with the upper part of a double-deck main flue. As the fume contains very little free acid, it was found difficult to obtain a good clearance in the Cottrell treater. It was found necessary to add moisture by means of a series of sprays. These at first were placed too near each other, so that they formed drops, thereby defeating the purpose, which was to create a mist. A spray-chamber was built. The sprays used now are made by the Spray Engineering Co.; they require 45 gal. of water per minute under a 225-lb. pressure. It is necessary to have this water filtered so as to keep the fine screen in the sprays from choking and to keep the sprays at maximum efficiency. The gas is cooled from 225° to 105°F., the relative humidity being about 50%.

THE COTTRELL TREATER consists of four sections, each of which has 64 pipes made of riveted steel, 12 in. diam. and 16 ft. long. The principle of the Cottrell tube is the electrification of suspended particles by the discharge of high-potential electricity into a stream of gas or fume. The individual particles become charged electrically so as to cause them to be attracted by the opposite polarity of the steel tube or pipe. The electric current is conducted within the pipes by a wire or chain made of No. 12 iron wire. The first step in the operation is a discharge of free electricity from the wire or chain into a stream of fume; these charges of electricity are immediately condensed upon the particles of dust, which then become repelled by the wire or chain, which is electrically of the same sign, and attracted by the wall of the steel pipe, which is of the opposite sign. The dust drops when it has accumulated thickly, but this detachment is expedited by rapping the pipes every two hours, which is done by a series of hammers suspended on a bar so that the movement of the lever causes them to hit the pipes.

The humidifying chamber is protected by a coating of gunite; nevertheless the flue shows the stains made by the acid produced by the reaction between the spray and the fume. When nine roasters are in operation the volume of gas is 140,000 cu. ft. per minute, and this gives a velocity of 11 ft. per second in the pipes. The treater was designed for five roasters, but the D. & L. plant has been increased to nine roasters, so at the present time the treater is somewhat over-crowded. On account of their acidity and temperature the roaster gases would be severe on the bags of the bag-house, consequently it has been found much more satisfactory to treat the roaster gases in the Cottrell treater.

The electrical equipment of the Cottrell treater consists of three rectifiers. The rectifier is mounted on the same shaft with the motor and generator. The current goes from the generator to the transformer of the rectifier, so that a direct current is supplied. The primary voltage is from 200 to 220, and the transformer ratio is about 436. The voltage used in the treater varies from 80,000 to 100,000. The rectifiers are arranged so that, by a series of switches, any rectifier can be used on any combination of treater sections. At the present time one rectifier is taking care of four sections. The motors are 25 hp. and the transformers have 10 kva. capacity. The field current for the generators is derived from a small motor-generator set. The steel outlet-flues were gradually eaten away by the moist roaster gases. These steel flues were replaced about a year ago by wooden flues made out

were filled with coke, one with coke-breeze, and one with antimonial skimmings. This list of contents suggests the variety of materials fed into the furnaces of the smelter.

The limestone comes from Ione, in Washington, on the Metaline branch of the Chicago, Milwaukee & St. Paul railroad and about 220 miles from the smelter. The Caledonia ore contains about 22 oz. silver, 6% copper, 6% lead, and 70% silica.

Each bin has two discharge-chutes, the material being held back by an ordinary arc-gate. Underneath each chute is a steel weighing-hopper, which is suspended from a Fairbanks scale. The man in charge of the weighing keeps in the several hoppers the exact amount of material required to make a complete charge for the furnaces. The ore, roast, flux, and coke, after being thus weighed, are discharged into the charge-car by the hopper-man,

Fig. 6

of two-inch surfaced tongue-and-grooved stock. There are four of these outlet-flues and their cross-section is 30 in. by 9 ft., inside measurement. They are painted with P & B on the inside. The wooden flues have proved most satisfactory, and no more trouble has been experienced from leakages.

In the west gulch are the 24 charge-bins. The eight eastern bins are built of concrete and have a capacity of 3600 cu. ft. each. The central eight wooden bins, for silicious ores and limestone, have a capacity of 3500 cu. ft. each, and the western eight wooden bins are for coke, of which each holds 60 tons. On September 17, 1920, the date of my first visit to the smelter, five of the concrete bins held Dwight & Lloyd sinter, one contained flue-dust from the bag-house, and two were filled with slag. Of the wooden bins, two held limestone, two were filled with middling rich in siderite (iron carbonate), one contained flotation concentrate, two contained silicious ore from the Caledonia mine, one held dross from the lead refinery, six

who travels with it. The car contains two compartments, each of which holds a complete charge, weighing about two tons; it is hauled by a four-ton electric-trolley locomotive, which runs on a standard-gauge track to the blast-furnaces.

BLAST-FURNACES. There are four of these, each being 48 by 180 in. at the tuyeres. The crucible is 45 by 180 in. The furnaces have two tiers of steel water-jackets, the only brickwork in the column being a 6-in. filler of brick between the top of the second tuyere-jackets and the cast-steel top, which extends to a point about seven inches below the feed-floor. The feed-opening is 27 in. by 13 ft. The blast-furnaces have five jackets on each side and each jacket has two 4-in. tuyeres. The blast is supplied by a Connersville blower and the furnaces are usually run at a pressure of 32 oz. per square inch. The blower has a capacity of 100 cu. ft. per revolution and is driven at a speed of 145 r.p.m. There are also two Ingersoll-Rand turbo-blowers that have a capacity of 12,000.

cu. ft. each, and are driven at the rate of 47 r.p.m. These turbo-blowers work very satisfactorily in conjunction with the positive blower, and will take up any variation of load, so that the elements of pressure and volume can be regulated to a nicety. Each furnace uses between 6000 and 7000 cu. ft. of air per minute when smelting about 300 tons of charge per 24 hours. The charge normally is as follows:

	%
'Roast'	65 to 70
Limestone	4 to 5
Dross	5
Return slag and clean-up	3 to 4
Middling	5
Flotation slime	2½
Sintered flue-dust	5
Caledonia ore	7

To this is added coke in the proportion of 11 to 12½%. Such a change as the above (taken from the record for one day) would average 30 to 35% in lead. It would take about four hours to go through the furnace. The slag is run into two settlers, one of 6-ft. diameter made of cast-steel 2½ in. thick, overflowing into another of 5½ ft. diameter made of cast-iron, one inch thick, and discharging into a Treadwell pot of 130-cu. ft. capacity. The slag-pot is handled by a 10-ton electric-trolley locomotive operating on a standard-gauge track. The lead is running off the furnace all the time except when the slag-level is lowered by tapping, and flows into a 4-ton brick-lined cast-steel pot riding on a car pulled by a crane, the pot being then lifted and emptied into the drossing-kettle, of which there are four, each of 50 tons capacity. The matte is tapped from the settlers into 4-ton cast-steel pots similar to the bullion-pot, and is also handled by the traveling crane. The charge-column is maintained at a height of about 8½ ft. above the tuyeres. The fume from these furnaces passes through steel flues underneath the feed-floor into a large settling-flue situated south of the blast-furnace building and extending a little west of the lead refinery. Here the settling-flue makes a 45° turn up-hill toward the bag-house and stack, and is gradually reduced in size. The cross-sectional area of the settling-flue, which has a 45° bottom, is 17 by 15 ft. The cross-section of the main flue going up the hill to the fan-house is 12 by 11 ft. 10 in. The fume is sucked by a large fan (of which there are two, one being held as a spare) to the bag-house.

THE BAG-HOUSE is built of brick and is 129 ft. long, 56 ft. wide, and 49 ft. 6 in. high to the eaves. The thimble-floor is 14 ft. 6 in. above the ground-floor, and above the thimble-floor the bag-house is divided into three sections, each containing 400 woolen bags, 30 ft. long and 18 in. diam., suspended in the line of their length. The bags are shaken every two hours by means of an eccentric device placed at the top of the bag-house and operated by an electric motor. While this operation is taking place in one compartment, the smoke is going through the other two. Usually, only two compartments or sections are used at the same time. The bags will last five or six years, when they will have to be replaced on account of leakage due to corrosion caused by sulphuric acid. Each section

below the thimble-floor is divided into four chambers. The flue-dust is set on fire in these chambers and sintered. It contains about 74% lead and 8% sulphur. The bag-house also receives the fume from the furnaces of the lead refinery and the silver refinery. However, there has been a tendency in the summer-time for the bag-house to get very hot, so that it is proposed to treat the refinery fumes in the Cottrell plant as soon as it has been enlarged. This will make a flexible arrangement.

THE LEAD REFINERY is an extension of the blast-furnace building, the total length of which is 396 ft. This building is served by two 20-ton Pawling & Harnishfeger traveling electric cranes. There is also a 10-ton crane in the west end of the building for use in case one of the other cranes becomes unavailable.

The equipment of the lead refinery is as follows:

Four 50-ton drossing-kettles,
Three 75-ton softening-furnaces,
Four 50-ton desilverizing-kettles,
Three 75-ton refining-furnaces,
One 200-ton circular merchant furnace,
One 30-ton by-product or residue furnace,
Two Miller casting-machines,
Eight retorting-furnaces.

This equipment is sufficient to treat 225 tons of refined lead per day. The molten lead from the blast-furnace is discharged, as described, into a cauldron the heat of which is brought up to 1000°F. so as to melt any free lead that may be in the dross, which is then skimmed off by a Howard press, a device invented by W. H. Howard of the American Smelting & Refining Co. This separates the molten metal entangled in the scum or dross. The fire is then taken off and air is blown into the kettles so as to oxidize the copper, which comes to the surface on account of the agitation, also forming a dross that is skimmed by the Howard press. The temperature of drossing is about 650°F. and the air is introduced until the lead almost freezes on top. The first skimming yields a dross containing about 80% lead and 15% copper, besides some sulphur and antimony. The copper content, of course, will vary according as the blast-furnace bullion is high or low in copper. The second skimming yields a product containing about 65% lead and 15% copper. When this operation is completed the lead will contain only 0.06% copper. The lead is then heated so that it can be pumped into either one of the three softening-furnaces. An ordinary centrifugal pump is used and the lead is carried to the softening-furnaces in a launder 75 ft. long made of ½-in. boiler-plate with a lining four inches thick on each side, and five inches thick on the bottom. The lining is made of a mixture of two parts cement and five parts limestone, which should be of the size of coarse sand. The mixture is put into the launder as dry as possible and is well tamped. The idea of this launder is credited to John F. Miller, who had used it at Port Pirie, Australia. The launder is a very poor conductor of heat, so that during the pumping operation the lead runs nicely with a very slight fall into the furnaces, and there is practically no lead left in the launder when the operation is completed. The launder is not covered, and the opening is five inches wide.

In the softening-furnace the arsenic and antimony are removed. This usually takes about 20 hours, as the bullion contains around 1% antimony. It is necessary to bring the temperature of the lead in the furnace up to about 1650° F., when the antimony starts to oxidize, and the heat is cut down slightly. After sufficient antimony has risen to the surface and oxidized in the form of lead antimonate, the doors of the furnace are thrown open, the fire is taken out, and the bullion allowed to cool. The antimonial slag solidifies and is rabbled out of the doors. This material is sometimes caught in slag-pots; at other times it is dumped on the floor. The skim contains about 70% lead and 14% antimony.

When the bullion has thus been softened it is tapped into the de-silverizing kettles. The dross is skimmed and put back into the softening-furnace. Some fresh zinc, and that returned from the last operation on the preceding batch of bullion, is added. The underlying idea of

silver into as small a bulk of alloy as possible. The gold recovered at this stage is derived chiefly from the concentrate shipped from the Alaska Juneau mill in Alaska. It takes two operations to eliminate all the gold and silver. The desilverized lead contains 0.6% zinc, which has to be burned off in the refining-furnace. At the same time any remaining traces of arsenic and antimony are collected in the dross, leaving the refined lead ready for the merchant furnace, from which it is made into pigs by the Miller casting-machine. See Fig. 7. This was invented by John F. Miller, formerly superintendent of the lead refinery at Trail, B. C. It is necessary to eliminate the copper from the lead bullion because the copper has a greater affinity for zinc than for the other metals, consequently zinc will be wasted if the copper is not eliminated. The concentration of the zinc crust is between 45:1 and 50:1. The zinc-silver-gold crust is dumped into a bin at the retort

FIG. 7. THE MILLER LEAD-CASTING MACHINE

the zincing is the separation of the gold and silver by their preference for zinc rather than for lead. This is the old Parkes process. An alloy of gold, silver, copper, lead, and zinc, is formed and it rises to the surface of the lead, to be skimmed into a Howard press, which squeezes the lead out of the crust (a zinc-lead alloy containing 2000 oz. silver per ton) while this machine is suspended over the kettle (which has a capacity of 50 tons) by means of a crane. When the operation is finished, the crane swings the press to one side and dumps the crust, which is then broken by crowbars and shovels before it solidifies; then the press is returned to the kettle, the operators skim the bath of metal and ladle the crust into the press as before. One man holds the skimmer, a flat spoon, while two others employ wooden pushers to move the crust into the spoon. The zinc is stirred in by a double-shafted stirrer, the temperature being about 975° to 1000° F. The zinc-silver mixture is skimmed in the same manner as the lead dross, except that it is necessary to have a good pressure of air so as to squeeze all the lead possible out of the zinc crust, as it is necessary to concentrate all the gold and

department, where it is drawn into a car and weighed in 1200-lb. charges. The skim is then shoveled into either a No. 9 Dixon retort, or a No. 30 Jonathan Bartley retort. Each retort is set in a Faber du Faur tilting furnace, in which the zinc is distilled. Pulverized coal is the fuel. The operation takes about seven hours. Old retorts are used as condensers and the zinc is drawn off at intervals, as it condenses, into steel-plate molds. The operator can tell when the zinc has been volatilized by pulling out an iron rod that fits into the hole in the top of the condenser. If any zinc remains, a blue-green flame appears. However, this operation has to be carefully done, otherwise there will be considerable loss of zinc, due to the burning of the metal. The zinc that is recovered is used again in the Parkes kettles. At the outset the desilverizing was done with zinc made at Great Falls, Montana. When the operation is completed, the condenser is pulled aside and the residue, called retort metal (consisting of lead containing the gold and silver, with traces of zinc, copper, and other impurities), is tapped, by tilting the retort, into a ladle, amid plenty of white smoke and blue-

green spurts of flame produced by the combustion of the zinc. A shower of snow—zinc oxide from the oxidation of the fume—falls all around. After the retort metal has been tapped into a tilting ladle it is poured into molds in the form of a bright cherry-red stream that gradually

coal in keeping the condensers cool enough, so that all the zinc vapor is condensed. A. Donaldson, the foreman of the refinery, inserted a 3-in. tile through the centre of the condenser. When the condenser is too hot the clay blocks are taken out of the ends of this tile, thereby exposing

darkens to a ruby tint, and finally to a leaden look. Then the furnace is tilted back and another charge is shoveled into it hastily. This is done by hand as rapidly as possible in order not to waste any heat and to avoid unnecessary burning of the zinc.

Difficulty has been experienced when using pulverized

more surface to the fume. This idea has been most successful. A setting of the retort is shown in Fig. 8. The pulverized coal is fed through the top of the brickwork and the gases are taken out on the side, although some of the settings are slightly changed so that the gases of combustion can be taken out through a flue in the centre at

the back of the retort. When pulverized coal was substituted for fuel-oil, it became necessary to lower the bottom of the retort-setting about six inches. This gives space for the slag from the ash in the coal to accumulate and also gives a chance to pull the slag out when the metal is

retort is to be used, it is taken from the upper flue, placed immediately in its setting, bricked up, and fired at once, so that the retort is not allowed to cool. This practice has lengthened the life of the retorts, the average endurance being 35 heats, although on a trial of six special retorts,

LEAD CASTING-WHEEL AND MERCHANT KETTLE

ANOTHER VIEW OF THE LEAD CASTING-WHEEL

ing poured from the retort. The flue carrying the
ses of combustion is made in two sections, the upper
e, which is used for annealing the retorts, being covered
th steel plates. Holes in the arch of the lower flue
low the heat to circulate through the upper flue, thereby
rving to anneal the retorts thoroughly. When a new

under working conditions, an average of 82 heats was obtained.

The retort metal contains 2500 oz. silver per ton and it requires seven hours to remove the zinc by distillation from the charge of 1200 lb. of zinc crust. The recovery of the zinc ranges between 80 and 85%. The retort metal

is then refined by cupellation in the silver refinery.

THE SILVER REFINERY. Here the lead and other impurities in the retort metal are separated from the silver in a cupelling furnace of the type designed by Frank Rhodes, formerly at the Omaha smelter. Heat is supplied either by the burning of pulverized coal or of fuel-oil. A blast of low pressure, about three ounces per square inch, serves to hasten the oxidation of the lead, which, as litharge, is skimmed into small slag-pots, using a splitting-plate of cast-iron, thereby aiding the recovery of small particles of metal in the litharge. The metal that remains in the furnace is an alloy of gold and silver called doré; it is poured into molds by tilting the cupel, which will contain about 60,000 oz. at a time. The bars of doré weigh about 500 oz. Troy. The cupel itself is lined with a mixture of five parts limestone, three parts clay, and two parts cement. The limestone is crushed to the size of coarse sand. These materials are mixed thoroughly with a little water and tamped very carefully into the frame of the cupel. Around the sides there is a lining of magnesite bricks placed on end.

The doré ingots, in charges of 10,000 oz., are parted in cast-iron kettles by means of sulphuric acid of 66°B. strength. The silver is dissolved and the resulting silver-sulphate solution is drawn into lead-lined vats. Here copper bars are suspended in the liquor by means of 'corrosion' hooks and steam is introduced so as to cause the solution to boil. The silver is precipitated on the copper, which in turn goes into solution as sulphate; the silver is deposited in the form of 'cement silver', which is filtered, washed in boiling water, dried, and then melted in a Monarch double-chambered tilting furnace, fired by oil. The silver is 999 fine; it is cast in bricks of 1250 oz. and shipped by express to San Francisco. In producing 1000 oz. of silver it is customary to use 125 lb. of acid and 21 lb. of copper. The insoluble residue, after the silver has been dissolved in the parting-kettle, contains the gold in the form of a brown powder, which is boiled to remove any sulphates and is then melted in a graphite crucible, as at Selby.[†]

The copper solution is pumped to an adjoining building, where it is evaporated sufficiently to cause the copper sulphate to precipitate in crystals; these are re-dissolved in water and again crystallized on strips of lead in another lead-lined vat. The copper sulphate is pretty stuff, and remarkably pure; it is an industrial sapphire that deliquesces readily; it is sold either to the farmers, who use it for spraying, or to the flotation mills. For a time it found a local market at the Interstate Callahan mill, now idle, which used a selective-flotation method. The mother liquor is evaporated to 66°B. and put back into the main acid-storage tank.

In the lead refinery there is another reverberatory furnace, named the residue or by-product furnace, in which the different drosses are treated. The products from this furnace are lead bullion, copper matte, and an antimonial slag. Galena is added to this furnace to supply the sul-

phur required to put the copper into a matte, which contains 25% copper and 40% to 50% lead. The antimonial slag contains 50% lead and 18% antimony; it is smelted in one of the blast-furnaces with an equal amount of blast-furnace slag, together with refinery-furnace drosses and lead ore poor in silver. The antimonial content of the 'hard lead' is controlled so as to suit the requirements of the trade. The Bunker Hill 'hard lead' contains 18% antimony; it is the base of most of the common anti-friction metals, as well as of the type used in printing.

The dimensions of the steel pans for the reverberatory furnaces in the lead refinery are 21 ft. long, 12 ft. wide, and 3 ft. 4 in. high. The distance from the bottom of the pan to the top of the brick arch is 6½ ft. The brick-work is protected by water-jackets made out of 15-in. channel-irons and ¼-in. plate, which is welded to the channels. The length of the side jackets is 20 ft. 6 in. and the length of the end jackets is 11 ft. 6 in. There is also a simple flange and clamp used for connecting pipes through which lead is to be pumped. The clamp is arranged so that by tightening one bolt the flange is made tight. This is convenient, as the pipes and clamps are quite hot and the old-fashioned flanges and clamps are very awkward to handle. It takes some time to break the old flange, and in the meantime the lead is likely to solidify in the pipes. The credit for this coupling is due to Louis Anderson, the head pipe-man, an old employee of the Bunker Hill Co. This flange and coupling are shown in Fig. 9.

The coal-pulverizing plant has the usual Bonnot equipment. The screw-conveyors, under the storage-bins discharge onto a belt-conveyor running under an electric magnet and into a weighing-hopper. The coal is then fed into a 4 by 30-ft. dryer, which is fired direct, and from here the coal is conveyed by a screw-conveyor to two one-ton storage-hoppers over two Bonnot pulverizers. The pulverizers have a capacity of 1½ tons per hour. The fine coal is sucked by a fan from the pulverizer into the main storage-bin, where it is settled by a Bonnot 'collector'. There is one distributing fan for the silver and lead refineries, and another for the D. & L. roasters. An air-float valve regulates the speed of the motor that drives the screw-conveyors from the main storage-bin into the distributing fans; it is arranged so that when more burners on the line are opened, more air is supplied there; consequently, this float-valve accelerates the screw-conveyors and increases the quantity of coal fed into the line, and, similarly, when coal-burners are turned off the quantity of air drawn is lessened and the speed of the screw-conveyors is decreased. Thus the mixture of air and coal is kept constant. The mixture in the distributing pipe is 50 cu. ft. of air to one pound of coal, and an additional 150 cu. ft. of air is supplied at the furnace by an auxiliary blower in order to make perfect combustion. About 85% of the pulverized coal will pass a 200-mesh screen.

The average consumption of fuel-oil on the D. & L. roaster is 1½ gal. per ton. This figure takes into account only the actual tonnage of material roasted, and does not

[†]The Selby Smelter, by T. A. Rickard, 'M. & S. P.', April 8, 1916.

allow for the extra tonnage caused by double-roasting some of it. The same work used to be done by 7 lb. of pulverized coal.

A saving of time was made when pulverized coal was substituted for oil on the retorts. The average quantity of oil used on the charge was about 44 gal., whereas the

gives the smelter an ample supply of domestic water. The smelter and Sweeney mill are protected by an electric system of fire-alarms. First-aid cabinets are maintained all through the plant, and it is a strict rule that all cuts, no matter how slight, must be immediately dressed, so as to avoid any possibility of blood-poisoning. The smelter has its own sewerage plant.

M. H. Sullivan is superintendent, A. F. Beasley, assistant superintendent, S. Butler, general foreman of the roasters and blast-furnaces, A. Donaldson is foreman of the refineries, J. B. Schuettenhelm is in charge of the Cottrell treater, roaster charges, and testing department, P. C. Feddersen is chief chemist, and G. C. Gage is in charge of the smelter office.

NOTES. A few further scattered notes may be added: During the War the smelter was enclosed within a barbed-wire fence and protected by armed guards. No trouble, however, was experienced. At

LEAD INGOTS IN RAILROAD-CAR

quantity of pulverized coal is 680 lb. In the lead refinery 15 lb. of coal is used per ton of refined lead.

The slack coal is purchased from the Central Coal & Coke Co. and the Gunn-Quealy Coal Co. It comes from Rock Springs, Wyoming, which is 1030 miles distant. The coke comes from Sunnyside, Utah, 1080 miles from the smelter.

Recording pyrometers, thermometers, and pressure-gauges regulate all operations. The smelter has a four-wheel Link-belt locomotive-crane that moves all the coke and limestone into stock, besides shifting the slag, matte, and dross. There are also three locomotives, the newest one a six-wheel American locomotive, weighing 60 tons and oil-fired. Nineteen steel cars owned by the company are used in the daily operations; most of these being employed for moving the ore & L. roast, either to the sampling-mill, for re-crushing, or to the charge-bins. The

at that time most of the Bunker Hill silver went to the Orient, for paying the Indian cavalry that conquered Mesopotamia for the British. The lead was sold chiefly to the Chinese, the special pigs, weighing 200 lb. apiece,

A WAGON-LOAD OF SILVER; 65 BARS WORTH \$83,147

The smelter has three water systems, for domestic purposes, furnace use, and fire protection. The valves on the centrifugal pumps are arranged so that water can be drawn from any source of supply and pumped into any of the distributing lines. The water is obtained from the Bunker Hill system, and there is also a new 12-in. water-line that has just been laid in Government gulch, which

destined for China being marked with Chinese characters instead of the usual stencil; they were shipped by the Robert Dollar Company from Seattle.

On the day of my first visit only one blast-furnace was running; usually two are kept busy. The four furnaces could treat all the lead ore produced in the Coeur d'Alene, their capacity being out of proportion to that of the refinery. It is comfortable for the men to have an

idle, and cool, furnace on either side of the one they are tending. On the charge-floor a Bristol recording thermometer registers the temperature of the gases discharged from the furnaces; it serves also to record the number of charges, by means of the dip on the chart made at the moment when a car is dumped into the furnace.

It is pleasant to stand before the blast-furnace and watch the stream of molten lead pouring into the kettle and then watch the slag being tapped from a higher outlet, with much spluttering, into a pot. The slag-dump, after only three years of operation, already fills the eastern gully and upon it there has been built a garage to hold the six automobiles used by members of the staff.

The final casting of the refined lead is likewise attractive. The market lead is pumped into the casting-machine, the overflow running back into the kettle. The division between the molds produces a superfluity. The metal in the conducting-pipe is kept hot by means of an electric heater consisting of a coil of wire around the pipe. The casting-machine is a wheel, water-jacketed inside and outside; on its periphery are the molds. The lead is pumped through a hole in the outer water-jacket, so that by the time a mold comes round to the bottom the metal in it is cool enough to fall out, being loosened by natural contraction. The pigs are stenciled 'BUNKER HILL'; they are weighed and check-weighed before being loaded into a railroad-car. The tally shows the destination of the shipment. The one I read was to "Hoyt Metal Co., Perth Amboy, N. J.", and bore the further inscription: "This car contains B. H. lead 99.99 per cent pure". As the pigs of lead fall with a dull thud upon the loading-truck it is a satisfaction to realize the end of the many and varied operations through which the metal has passed on its way from the rock in the mine to the railroad-car at the siding.

The lead from the Bunker Hill goes direct to the consumer. Other mining companies in the Coeur d'Alene have to follow a more devious procedure; for example, the Hercules concentrates its ore at Burke, Idaho; smelts it at Northport, Washington; and refines the bullion at Carnegie, Pennsylvania. The astonishing diversity of the industries using lead is suggested by the following list, given to me by Mr. Bradley, from among those who buy the Bunker Hill lead:

Remington Arms U. M. C. Co...Bridgeport, Conn.
Simplex Wire & Cable Co.....East Cambridge, Mass.
The Okonite Co.....Dundee, N. J.
Ford Motor Co.....Detroit, Mich.
Conley Foil Co.....New York, N. Y.
Peters Cartridge Co.....Kings Mills, Ohio
Union Sm. & Ref. Co.....Newark, N. J.
Ellenwood & Doyle.....New York, N. Y.
Norton Company.....Worcester, Mass.
Grasselli Chemical Co.....Grasselli, N. J.
Matheson Lead Co.....Long Island City, N. Y.
Robert Dollar Co.....Hankow, China
E. I. du Pont de Nemours Co....Newark, N. J.
Standard Underground Cable Co.Perth Amboy, N. J.
Electric Storage Battery Co....Philadelphia, Pa.

Anaconda Copper Mining Co....Black Eagle, Mont.
Pacific Metal Works.....Portland, Ore.
W. H. Harrison.....Great Falls, Mont.
Latimer Goodwin Chem. Co....Grand Junction, Colo.
Eagle Picher Lead Co.....Cincinnati, Ohio
Winchester Repeating Arms Co..New Haven, Conn.
Standard Tin Foil Corp.....Philadelphia, Pa.
Great Western S. & R. Co.....San Francisco, Cal.
Pacific Metal Works.....San Francisco, Cal.
Nathan Trotter & Co.....Philadelphia, Pa.
General Electric Co.....Schenectady, N. Y.
Crescent Adams & Co.....Chicago, Ill.
U. S. Foil Co.....Louisville, Ky.
Hendrie & Bolthoff.....Denver, Colo.
American Brass Co.....Kenosha, Wis.
Cutler Bros.New York, N. Y.
Standard Rolling Mill Co.....Brooklyn, N. Y.
Carnegie Steel Co.....Pittsburgh, Pa.
Northwest Lead Co.....Seattle, Wash.
Gardiner Metal Co.....Chicago, Ill.
National Lead Co.....Brooklyn, N. Y.
Windsor Mfg. Co.....Milwaukee, Wis.
Sherwin Williams Co.....Kensington, Ill.
Hazard Mfg. Co.....Wilkes-Barre, Pa.
Wensley Metal Products Co....Denver, Colo.
John Wahl Commission Co.....Utica, N. Y.
A. Wilhelm Co.....Reading, Pa.
American Rolling Mill Co.....Middletown, Ohio
Michigan Sm. & Ref. Co.....Detroit, Mich.
Rockwood Sprinkler Co.....Worcester, Mass.
General Fire Extinguisher Co..Atlanta, Ga.
United Lead Co.....Perth Amboy, N. J.
Hoyt Metal Co.....Perth Amboy, N. J.
Carnation Milk Products Co....Kent, Wash.
Metals Warehouse Co.....East St. Louis, Ill.
Adam Hope & Co.....Hamilton, Ont.
Lima Locomotive Co.....Lima, Ohio
Southern Pacific Co.....Sacramento, Cal.
Doehler Die-Casting Co.....Toledo, Ohio
Norfolk & Western R. R. Co....Roanoke, Va.
Louisville & Nashville R. R....So. Louisville, Ky.
United Iron & Metal Co.....Canton, Ohio
Nat. Transit Pump & Mfg. Co...Oil City, Pa.
Chicago Bearing Metal Co.....Chicago, Ill.
Hammer Bros. White Lead Co...East St. Louis, Ill.
Standard Sanitary Mfg. Co.....Louisville, Ky.
National Conduit & Cable Co...Hastings-on-Hudson, N. Y.
H. Kramer & Co.....Chicago, Ill.
Washburn Wire Co.....117th St., Harlem River
N. Y.
Safety Insulated Wire & Cable...Bayonne, N. J.
White & Bros., Inc.....Philadelphia, Pa.

The names of the buyers indicate the various uses to which they put the lead, namely, for shot, bullets, bab bitt and other anti-friction alloys, lead foil, sheet lead pipe, casing for electric wires, white and other paints lining for acid-vats and electrolyte cells, solder for cans and plumbing supplies.

The smelting at this plant is characterized by a high proportion of lead in the charge, from 30 to 35%, and by a very low zinc content, averaging less than 4%. Looking at this extensive and comprehensive smelting plant, it is pleasant to realize that there is a splendid productive mine back of it.

Notes on Mining in British Columbia During 1920

Special Correspondence

There can be no doubt that the weakness of the copper market is having its effect on the industry in British Columbia. How serious this is to be depends entirely on the length of time it takes for world conditions to adjust themselves. It serves no good purpose to attempt to blind ourselves to the facts; the outlook is not promising. With the Granby company's forces at Anyox materially reduced; with the Britannia Mining & Smelting Co., according to authentic report, devoting itself to development of its properties to the exclusion of production and shipment, with a cutting down of the working force; with the Canadian Consolidated Mining & Smelting Co. at Trail declaring that only necessary construction will be proceeded with; and with the Canada Copper Co., whose Copper Mountain mines at Allenby are just ready for production, announcing that operations must cease until the market improves, it is clear that the large producers have concluded that it is impossible to produce copper at a profit at the present time.

That many of those in close touch with the situation declare that it cannot last for long, and that as soon as copper climbs back to its normal place all these companies will resume both production and development, constitute the silver lining to the cloud. In passing, it is interesting to direct attention to the paramount importance of copper in considering mining in this Province. When that metal slumps, its effect is serious wherever there is a mining industry, but in this Province the result is calamitous, as, being without an iron and steel plant of consequence and there being no production in iron, it hits at the very backbone of the industry.

Taking the year 1920 all through, up to the middle of December, British Columbia has not done badly in point of the production of its metal mines. From the general information available, it appears that the output of copper for the twelve-month will be about equal to that of 1919, that is, 42,459,339 lb. For the first nine months of the year, it must be borne in mind, the larger companies, for the most part, maintained their production at a high level. The Britannia Mining Co., for instance, milled as many tons of ore as it did in 1919 before the copper market fell into the doldrums. The price having fallen to 14c. per pound in New York, production was cut down, otherwise the tonnage treated by flotation in the concentrating mill at Britannia this year might have established a new record for the plant. These latter observations tell the story of the operations of the Granby Consolidated Mining & Smelting Co. at Anyox. Not until the latter part of the year was the output reduced, so that it is expected that the figures for the period will not be unfavorable in comparison with those of the previous year.

As to the Consolidated Mining & Smelting Co., at Trail, it is not at present a large producer of copper. Its returns in this respect are likely to be unfavorably affected because of the fact that the Rossland mines have not been shipping largely. With a number of independent shippers, although none contributing in quantity and regularly, and with some shipments of importance from the Mandy mine of Manitoba, the Trail smelter returns, however, may contain a surprise.

This company, in a greater degree than heretofore, is turning its attention to copper. The construction of concentrating plants at the Old Sport claims, on Quatsino sound, and at the Sunloch, Jordan river, both on Vancouver Island, had been planned for 1920, but the cost of labor, supplies, and machinery were too high as compared with the average price of the metal and the projects were permitted to stand. A start on these plants may be looked for during the new year. The intervening time has not been lost, as development was continued; working openings have been driven on both properties and diamond-drilling so pressed that much greater reserves of ore have been exposed.

The Tidewater Copper Co., operating the Indian Chief group at Sidney inlet, Vancouver Island, is an enterprise to which special attention should be directed. Through the adoption of a definite policy this company has placed itself in a position to mine and ship considerable quantities of concentrate over a long period, with every prospect of developing further resources as the work continues. During the past two years a sufficient body of ore has been blocked out to furnish 300 tons for treatment daily for two years by a mill which has been reconstructed, enlarged, and improved. In connection with the latter, a battery of Peterson flotation cells and an electrical plant for driving all machinery, including the air-compressor, have been installed. Two creeks have been used for the generation of power; the necessary plant has been provided.

The Kamloops district will show a drop in copper production this year because of the closing down of the Iron Mask mine. This took place last April, and since that time a start has been made in the installation of a new water-system and other improvements to the plant. The shaft has been straightened, new concrete foundations to the head-frame provided, a new conveyor built from the shaft to the mill, and increased storage-tanks constructed for the treatment-liquids.

With reference to the 1920 production of gold, there probably will be a decline in comparison with the previous year. In placer mining there has been considerable activity in the Cariboo, and farther north and north-east. In 1919 the placers of British Columbia produced 14,325 oz. of gold. That the lode gold mining

will not show as satisfactory results as in 1919 is assumed from the fact that the Rossland mines have been quiet and the Nickel Plate mine had been slowing down for some time prior to the final close of the mine. This occurred some two or three months ago and was the result of high costs and diminished purchasing power of gold. It is not advisable, however, to make anything but a qualified prediction in respect to gold, because, while it is true that the Rossland mines have not been producing, it must be remembered that they did not do much in 1919; and, although it is a fact that the Nickel Plate cannot be depended upon for a large production, it should be borne in mind that there will be a considerably greater return in gold from the output of the Premier mine in the Salmon River district. The lode-gold production for 1919 was 152,426 ounces.

Notwithstanding that the silver production of the north-east coast of British Columbia, where is situated the Dolly Varden mine, will be substantially greater than in 1919, it looks as though the total 1920 output will be less than it was in the previous year. The whole of the provincial coast and the Boundary district will show about the same production for this year, or perhaps a little better than in 1919. If the figures are higher the credit will have to go to the Premier and the Dolly Varden mines, especially the latter, which has been operated on a large scale throughout the year and from which a large quantity of high-grade silver-bearing ore has been shipped. But the Slocan district will be found to be short in production, and, in order that the significance of this may be properly understood, it may be said that in 1919 the northern coast produced in silver, 920,413 oz.; the Boundary-Yale district, 231,599; East Kootenay, 274,134; and West Kootenay, 1,799,229. The total for the Province was 3,403,119 oz. The richest silver mines of West Kootenay are in the Slocan district. What have been the conditions responsible for the slump? Two circumstances have served to restrict output. One was the lack of labor in the early part of the year and the other the discontent which developed later among the miners, finally resulting in a strike called by the 'One Big Union'. If the workers aimed to tie up the mining industry they were successful beyond a doubt. The operators refused their demands with the one exception of the Silversmith company, operating the old Slocan Star, and for months only that property was active. The situation now has changed. The lumber business has fallen off, logging is at a standstill, and there are plenty of men for the mines. Latest advices are that work has been resumed on most of the well-known properties of the district, but the damage, as far as the year's production is concerned, has been done and the record of production will suffer.

The production of lead and zinc depends largely on the output of the Sullivan mine, of Kimberley, which is treated at the Trail smelter of the Consolidated Mining & Smelting Co. This mine has been extensively developed and it has been yielding greater quantities of ore so that it is possible the lead production of the

Province, which in 1919 was 29,475,968 lb., will be about the same for 1920. There is no doubt that there will be a falling off in the product of the Slocan district so that much depends on the showing made by the company's mines. In regard to zinc the same remarks apply, except that it would appear likely that 1920 will show an increased output of that metal. Again the Sullivan mine is responsible, zinc ores being largely mined at Kimberley during the past twelve-month. In 1919 East Kootenay produced 46,460,705 lb. of the total 56,737,651 pounds.

Taking it as a whole the foregoing is not as bright a review as it has been possible to give for several years, but it is not unsatisfactory. For some time exceptionally high prices in copper, silver, and other products of the minerals of this Province were enjoyed and the fullest advantage was taken of the opportunities thus afforded for development. Consequently the industry has advanced far beyond the point it had reached five years ago. The present slump in the market, the existing unsettled conditions, and the results, should not be viewed with alarm in view of the richness of British Columbia's proved resources.

AN AUSTRALIAN MINING SCANDAL. Quite a sensation has been caused throughout Australia with regard to what has transpired in connection with a mining property acquired and held at Badak, in the Malay peninsula, by Victorian speculators. The reports at first received regarding this property, based on extensive borings, taken first by one individual and subsequently supported by another, were to the effect that a very rich run of tin had been found. These reports were of such a nature that, as a result of the wildest speculation, £10 shares in the Victorian syndicate were sold at as high a figure as £2000. Soon afterward, however, following the receipt of very different reports, a change came over the spirit of the dream of the rash speculators, and now it is apparent that either a big mistake has been made or something equally, if not more, unsatisfactory has occurred. The latest report from Malay is by I. Boadle, who has been boring on the Badak property under the supervision of H. F. Scarborough, a representative of the Victorian company specially sent over to look into matters. Mr. Boadle says he put down 86 bores, all of which bottomed. He carefully measured and washed the material from each bore, but in no case, he states, could he find ground that would pay to work, and in many bores there was not even a trace of tin. In the meantime the Victorian company has taken the unusual course of asking the Melbourne Stock Exchange not to call the shares of the company 'on Change' until such time as authentic and reliable reports have been received from the company's general manager, who was then on his way for Penang, and the Exchange has expressed its approval of a suggestion that the State government should hold an inquiry into all the affairs of the Badak company with a view to placing the responsibility if it develops that any irregularities are proved.

Karl Eilers v. Guggenheims

The following reply to Mr. Eilers' charges was made by Edgar L. Newhouse, chairman of the board of the American Smelting & Refining Co., as a return to the petition for a writ of mandamus. We take it from the 'Engineering and Mining Journal' of January 1, having received no copy directly.

. . . The original election of Mr. Simon Guggenheim to succeed Mr. Daniel Guggenheim as president of the company on January 21, 1919, represented the free and unanimous choice of the directors of the company. It is not true that the board of directors were given no opportunity to express any wish in the matter. The re-election of Mr. Simon Guggenheim as president of the company thereafter likewise represented the free and unanimous choice of the directors, save in the case of Mr. Eilers.

It is true that since their association with the company the Messrs. Guggenheim, or some of them, especially Mr. Daniel Guggenheim, Mr. Murry Guggenheim, and Mr. Simon Guggenheim, have exerted a weighty influence in the counsels and management of the company. It is not true that the Messrs. Guggenheim, or any of them, dominated the directors and officers of the company in the injurious and objectionable sense in which the term is employed in the petition. Such position of influence and authority as they held was altogether due to their great abilities, their unusual knowledge of the business and their singular qualifications as directors in the enterprise. It was in no wise due to arbitrary methods or to artificial means of control. . . .

It is not true that the Messrs. Guggenheim, though continuing to act as directors, ceased to hold stock in the company except in a negligible amount. On the contrary, they have always been substantially interested as stockholders in the company.

The only member of the Guggenheim family who is now an officer of the company is Simon Guggenheim, who is president and is the owner of over 20,000 shares of the common stock of the company and, so far as deponent has been able to ascertain by investigation, is the largest single stockholder of the company, the total holdings of said Simon Guggenheim and his wife in common and preferred stock being in excess of 28,000 shares. Isaac and Daniel Guggenheim are directors but not officers, and draw no salaries. Their aggregate holdings of stock of the company are in excess of 8,000 shares. It is not true that any of the Messrs. Guggenheim ever received salaries from the company while not rendering commensurate service. . . . No salary is paid by the company to any of the Messrs. Guggenheim other than to the president of the company, Mr. Simon Guggenheim. . . . Especially it is denied that the Messrs. Guggenheim, or any of them, during their association with the company acted in disregard of the interests of the corporation or sought to employ it to serve their own ends.

The facts as to the company's activities in Bolivia are that prior to 1910 the company had never smelted tin nor had tin been smelted in the United States to any substantial extent by anyone. The company was then engaged in smelting and refining silver, copper, lead and other ores. In 1910 Messrs. Newhouse and Stewart, officers and directors of the company, went to South America for the purpose of obtaining contracts for the smelting of ores other than tin, at the company's plant at Tacoma, Wash. They did not while there investigate mining properties of any kind for purchase. While in Bolivia they became convinced that it would be to the advantage of the company to add the smelting of tin to its other smelting activities and upon their recommendation the company built a tin smelter at Perth Amboy, N. J., and entered into contracts with tin mines in Bolivia for the smelting of their ores and that business has been carried on up to the present time. It is true that a number of years later an examination of one or two tin properties in Bolivia was made for the company, but a majority of the board was opposed to the company's investing money in any tin mines in South America, and no such mines have ever been acquired by it. None of the property in Bolivia so examined for the company, or the purchase of which was considered by directors and officers of the company, was ever purchased by the Guggenheim Brothers, or by any member of that family. I deny that any demand was made by directors of the company that the company be allowed to share in Guggenheim Brothers' operations in Bolivia, or that any such demand was refused by the Messrs. Guggenheim.

With reference to the Premier silver and gold mine in British Columbia, the company's interest in making any investment therein was primarily to insure to itself the smelting and refining of the ore from that mine. Officers and directors of the corporation, other than the Guggenheims, were opposed to the investment of a sum of money as would be required to purchase a one-fourth interest in the mine which was the interest offered to the company by owners of the property. On the other hand, it was necessary for the corporation to arrange for the purchase of at least a one-fourth interest, if any interest was to be acquired, as the sellers did not desire to sell a smaller interest. The smelting company therefore solicited, through its Mr. Guess, the head of its mining department, the Guggenheim Brothers to purchase a one-half of the one-fourth interest offered, thereby relieving the company of the necessity of purchasing more than the remaining one-half of the one-fourth and this arrangement was informally approved by all of the directors of the company except possibly Mr. Eilers, and I have no recollection of Mr. Eilers ever objecting at the time or until this action.

The allegations of the petition in respect to sales of copper are incorrect and misleading. By far the greater amount of copper sold by all large copper producing and

selling companies is sold for future delivery, and owing to the custom of the trade and the requirements of the copper market, it is impossible for any company having a large output of copper to sell more than a comparatively small part of its production by current sales, such as are possible in other metals. Moreover, the volume of copper to be sold by the company has included, since about the year 1908, not only its own copper, but also copper sold by it as selling agent for a number of large copper producing companies, the selling agency arrangement having been made as part of arrangements to smelt and refine the ores of such companies, so that this company receives, in addition to its profit from its operations upon the ore, a separate and additional commission for the sale of the copper. The selling agency arrangement provided that the company sold its own copper, together with the copper of the companies for which it acted as selling agent, all sales of copper being pro-rated against the total amount of copper available for sale at any particular time, including the company's own copper. The net proceeds of the commissions paid to the company for its services as selling agent for other companies amounted, in the period from Jan. 1, 1913, to Sept. 1, 1920, to a sum in excess of \$10,000,000, and the conducting of such agency proved to be, during normal times, a source of large profit to the company. The existence of the agency, however, increased the necessity and volume of forward sales of the company's own copper, and particularly in the abnormal period following the outbreak of the European war it is true that some losses were suffered from this source. These quotational losses were due almost entirely to the existence of the selling agency. The statement made by Mr. Hills, the comptroller, as of Oct. 31, 1920, which is apparently the statement referred to at folia 28 of the petition, shows that from Jan. 1, 1912, to Oct. 31, 1920, the net proceeds from the selling agency amounted to \$10,046,409, and that from this should be deducted quotational losses incurred during the same period amounting to \$4,594,824, leaving an apparent net profit for the period on the operation of \$5,451,585. But this apparent profit will at present prices of copper be more than wiped out by quotational losses which will be suffered if the present dull copper market continues.

The statement that in April, 1920, as the result of a policy of withholding copper from sale, the company had on hand approximately 160,000 tons of refined copper is absolutely untrue. On May 1, 1920, the company had on hand for its own account 26,855 tons of refined copper. This accumulation was not due to any policy of withholding copper for sale, as the company had used its best efforts to sell all the copper it could, but was due, first, to lack of demand because of the fact that all consumers of copper were overstocked; second, to the fact that during the war production was greatly stimulated because of the war demand, and a large amount of copper ore came through after the signing of the Armistice in a volume much larger than during normal conditions; third, to the fact that labor and railroad conditions dur-

ing the war and after the signing of the Armistice were such as to lengthen the period between the delivery of ore to the company and the arrival of the refined copper at tidewater; and, fourth, to the fact that the company was not free to sell its own copper, independently of the copper of the companies for whom it acted as selling agent, since, under the selling agency agreements, the company's own copper had to be sold pro rata with that of all of the companies for whom the company acted as selling agent, and the aggregate amount which thus had to be sold was much greater than the market has been able to absorb during the conditions existing since the signing of the Armistice. All of these were conditions which were due to the abnormal times and for which the officers of the company were in no way responsible. The conditions experienced in these abnormal periods by this company have been common among companies in the same business.

The officers and directors of the company have from time to time during the past two years made efforts to work out a modification of the selling agency contracts which would leave the company the profits from its commissions as selling agent in normal periods and at the same time leave it free to sell its own copper independently during times of abnormal conditions, but although the greatest efforts were made by the company's officers to that end, this finally appeared not to be practicable, and as the end of the abnormal conditions are not yet in sight, it was determined by the board of directors during the month of November, 1920, to terminate the selling agency, which was accordingly done.

In other words, the company's selling agency was originally attractive and profitable to it, and during normal times resulted in large net profits accruing from the selling commission. The unprecedented abnormal conditions which arose during the war and again since the signing of the Armistice have created a situation which could not have been foreseen, and the result of which has been to offset quotational losses against the profits thus accruing, and no one can now foresee when normal conditions in the industry will return. The company's board of directors has, in order to prevent further losses from this source, deemed it to the advantage of the company to terminate the selling agency, so that hereafter the company will sell merely its own copper, unrestricted by obligations to sell the copper of any other company.

The various changes in the board of directors and in the officers of the company, referred to in the latter part of the seventh paragraph of the petition, took place, but the reasons therefor, and the inferences therefrom as stated in the petition, are wholly imaginative.

IT IS STATED that an American-owned manganese mine situated on the Gulf of California at Punta Aguja peninsula is now operating and is shipping 200 tons of high-grade ore monthly. The ore extracted runs from 20 to 92% manganese, averaging about 48%. Since the product is shipped to Chicago at present, it is impracticable to send other than high-grade ore.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

NEW EQUIPMENT AT THE KAY COPPER MINE.

PRESCOTT.—A receivership for the Consolidated Arizona Smelting Co. of Humboldt was granted in the Federal court at Tucson by Judge Sawtelle on December 24. The action culminating in the receivership was instituted by Francis S. Viele of Prescott and other creditors of the company. G. M. Colvocoresses, general manager for the company, was named by the court as receiver.

Final payment on the Stargo group of claims, 26 in number, from which shipments of silver and gold ore have been made continuously for the last 15 months to the smelters at Douglas, has been made, and the Stargo Mines, Inc., formed to receive title to the property. George J. Stoneman, president of the company, announced that about \$50,000 will be expended at once in development work in the lower levels with the expectation of justifying the erection of a 100 or 200-ton mill during 1921. This work will be carried on under the direction of William B. Ghoring, as consulting engineer, formerly superintendent of mines for the Calumet & Arizona Mining Co. of Bisbee.

Following the recent sustention of a demurrer to an injunction suit filed in Los Angeles in connection with the battle for the control of the Jerome Superior Copper Co., the plaintiffs have filed their action in the Yavapai county court. Counsel for those stockholders named as defendants in the suit, interposed the demurrer in Los Angeles on the ground that the court had no jurisdiction, as the corporation was of and in Arizona. The plaintiffs seek to bind the defendants from taking control of the corporation and of the corporation property. Officers and directors of the company are named as defendants.

KINGMAN.—Recent work done on the old Rawhide claim of Rawhide camp by Tony Hill and associates has opened rich silver ore, assays of which run 400 to 2000 oz. per ton in silver. A shipment of 140 lb. of the richest ore has been sent to the Selby smelter.

Operations, which have been suspended at the Arizona Mossback Mines Co. pending the overhauling of machinery, are to be resumed on the lower levels soon. It is reported that the company has sold half of its \$500,000 bond issue, the money from which is to be used for development and the erection of a mill.

MAYER.—Work at the Kay mine of the Kay Copper Co. was resumed on January 1; the new electric hoist has been installed. The power-line and other electrical equip-

ment is already in place. As soon as the installation of the hoist is completed sinking of the new three-compartment shaft is to be resumed.

WICKENBURG.—The Magewood Copper Mines Co. has taken over the Eva Consolidated Mining & Leasing Co.'s properties consisting of ten claims upon which there are said to be eight veins. The Magewood Copper Mines Co. is incorporated for 2,000,000 shares, 450,000 of which have been underwritten by the Standard Securities Co. of New York. Development work is to be done under the direction of Kirby Thomas of New York. About 500 ft. of development work has been done on the group and ore averaging \$26 per ton is said to have been opened. The property has been idle for some years.

COLORADO

RICH ORE DISCOVERED IN ASPEN MINES.

BRECKENRIDGE.—Ore assaying 2600 oz. silver and 70 oz. lead has been found in the June Bug lode. About one ton sacked by the lessees was shipped to obtain cash for celebrating Christmas. A shipment from the Auge lease on the Brooks-Snyder was settled for by the A. V. smelter, of Leadville, at \$700 per ton for first-grade, and \$50 per ton for second-grade ore. The Wellington Mines Co. has ceased operating its two mills, due to the low price of zinc, and is confining operations to mine development.

CENTRAL CITY.—Rich lead-carbonate ore, with silver averaging 300 oz. per ton, has been opened up on the After Dinner mine adjoining the Hard Money in the Hughesville district. The vein, struck at 50 ft., is reported widening. The operators, Hughes brothers and Swarthout, are installing machinery and plan to sink to a depth of 200 ft. Sinking is in progress at the Atlantic shaft at Hughesville, and will continue to 200 ft. Rich silver ore is saved from a vein in the shaft and in the 85-ft. level drift.

The Midwest M. & M. Co. has let a contract for a 300-ft. cross-cut tunnel starting from North Clear creek to connect with the Silent Friend shaft at 400 ft. Eight known veins, outcropping at surface, lie directly across the tunnel line. The Cyclops shaft is also to be drained to a depth of 400 ft. by the cross-cut, and with connection made an underground hoist will be installed and the Cyclops operated below the tunnel-level and ore taken to surface through the tunnel. The Midwest is also mining a good grade of ore in the Peruvia, and the Alaska mine, two miles distant, is under development. The ore

now being mined contains around 75 oz. silver and 10% lead. The ore is treated at the Iron City mill controlled by the Midwest, but a new mill will be constructed next spring in which flotation will be used.

CRIPPLE CREEK.—A gold brick weighing 102 oz., of estimated value of \$2100, was forwarded to the Denver Mint on December 15, from the mill of the Lincoln M. & R. Co., on Ironclad hill. This was the first bullion shipped. The mill is treating low-grade gold ore by the Gasche process. F. G. Gasche is manager for the company. Owen Roberts, former lessee of the El Paso Gold King, has taken a new lease on the Poverty Gulch mine, reputed the first producer of the Cripple Creek district. Twelve sets of sub-lessees started in with Roberts the first day. Roberts is also operating the Strong mine at Victor and, with a number of sub-lessees active, is shipping about 600 tons monthly of \$20 ore. Both mines are controlled by the Giddings-Lennox interests of Colorado Springs.

IDAHO SPRINGS.—The Humboldt property on Ute creek has been leased to local operators who are prospecting in one of the three tunnels on the property. Work is shortly to be resumed by lessees on the Columbia mine on Chicago creek. The Black Eagle on Chicago creek has been leased to Leadville operators who plan to operate the property through the Star tunnel. All three of the Idaho Springs mills are operating at capacity and report more ore delivered at their plants than for several years past.

ASPEN.—Excitement continues high over the discovery in the Hope tunnel and this has been enhanced by another important discovery in the Park tunnel. It is nearly a month since a high-grade seam was exposed in the Hope and the first assay returned 19 oz. silver. The entire breast of the tunnel is now in high-grade ore with neither wall yet determined. Late assays are reported to have shown 74 oz. silver, 29% lead, and some copper. The shoot has now been proved by a drift for 50 ft. and it shows no sign of decreasing in volume or value. Practically every railroad man running into Aspen or Leadville is interested and merchants in both Leadville and Aspen have steadily contributed to the Hope Tunnel development fund for the past twelve years and apparently their persistence is about to be rewarded. Eighteen inches of high-grade silver ore in the Jenny Lind runs as high as 180 oz. silver and the entire 2½ ft. of ore lying flat carries but little less. The orebody has been proved for a width of 35 ft. with the hanging wall not yet in sight.

LEADVILLE.—Leadville men have taken a three years lease on the Daly shaft of the Little Chief group on Fryer Hill. Sundry sections of the Pittsburgh, Little Chief, and Dives properties, included in the lease, will be developed. The lessees are experienced miners and are confident of opening a rich deposit of black iron. The triple-compartment shaft on the Daly is in need of repair and is being re-timbered and straightened. Few unpatented claims in Leadville have been neglected and the assessment work has in many cases been accom-

plished. A few old-timers will, however, be benefited by the relief measure passed by Congress and signed by the President just before the first of the new year.

MICHIGAN

REVIEW FOR THE YEAR 1920

HOUGHTON.—With the price of copper so low that few Lake Superior mines can make a new dollar while spending an old one, the mining companies of this district face a gloomy prospect for the new year. None of them looks for substantial improvement in the metal market until at least mid-year and it is certain that the present outlook from an operating standpoint is precarious.

The year end leaves the district with only the Calumet & Hecla, Copper Range, and Stanton groups, and the Quincy mine in operation. Only the conglomerate branch of the Calumet & Hecla proper is active, all Osceola lode shafts having been closed, and of the subsidiaries, the Ahmeek and Isle Royale are the only ones working. The Champion, Baltic, and Trimountain mines of Copper Range are producing 60% of normal, and Quincy also is on a 60% basis. Mohawk and Wolverine of the Stanton group are rapidly increasing production and will be back on a normal basis soon after the first of the year. Of the operating mines, Copper Range and Quincy are just about 'breaking even' on a 15c. copper market. Calumet & Hecla will finish the year with about 70,000,000 lb. of copper on hand. Copper Range and Quincy metal stocks are fully as large as a year ago, while Mohawk and Wolverine are cleaned up on copper, selling it about as fast as it is produced.

All companies in the district that have attempted to maintain production have been hard hit by unusual costs this year. The high price of fuel has been a big item. Coal that was purchased a few years ago and laid down at the docks here at a cost of \$3 per ton now costs \$10.50. The sharp advance in freight-rates also has hit some of the mines not owning their own railroads. As an illustration, one company is compelled to pay \$700 per day for the privilege of hauling ore to its mills, a distance of seven miles, while it pays \$100 per day for transporting coal from docks to mine. It means a big extra expense that adds materially to production costs. Calumet & Hecla and Quincy own their own railroads and are not affected by these high freight-rates, while Copper Range, which is a stockholder in the Copper Range Railroad company, which serves the Champion, Baltic, and Trimountain mines, gets some of its freight expenditure back in the form of dividends.

High costs have driven some of the smaller properties into idleness. The Franklin and Hancock have been closed for some months, and during the year Mass and Michigan also shut-down. None of the so-called Lake group of properties is doing any development work and Winona is closed. The recent curtailment policy of Calumet & Hecla also added the Osceola, Osceola lode shafts, Allouez, Centennial, La Salle, and White Pine to the list. Owing to the fact that the Calumet & Hecla curtailment

policy came late in the year, the production of the Calumet & Hecla group will not be much under the output of last year. Production will be slightly under 100,000,000 lb., while in 1919 it was 101,000,000.

Of the developing properties, Arcadian Consolidated, Seneca, and Mayflower continue in operation, with encouraging prospects of success. Particularly in Seneca and Arcadian the ground penetrated in sinking and drifting is uniformly and heavily mineralized, comparing favorably with any amygdaloid openings in the district, and a continuation of present content should put these properties in the producing class. Seneca announces a production in November of 82,451 lb. of refined copper from 2275 tons of rock taken out in course of development. This is an increase over October. The south drift is yielding splendid rock and the highly mineralized area in the north drift on the same level persists. In the third and fourth levels, north, good quality rock still is found, with the general outlook in that section uniform. In the Arcadian's New Baltic shaft, the outlook continues good. The shaft is now 800 ft. deep. A station has been cut at 719 ft., which corresponds with a depth of 750 ft. in the New Arcadian shaft. No drifting will be done on the lode, but the shaft will be sunk without a stop to a depth of 942 ft., at which point a drift will be driven to connect with the 900-ft. level of the New Arcadian shaft. This drift will be 3500 ft. long. Subsequently drifts will be extended from both shafts at points of contact with the lode. Mayflower's south raise, now 400 ft. long, is breasted in a mixture of trappy and mineralized matter. The raise in the east cross-cut, driven from the north drift, is in conglomerate formation and breasted in rock that is practically barren of copper. Four machines, operating two shifts, are at work on the two projects.

NEVADA

SUNDRY NON-METALLIC MINERALS ARE BEING MINED IN SOUTHERN NEVADA.

TULE CANYON.—Seven men are employed by the Silver Hills, which is operating the Ingalls mine under an option. It is reported that milling is to be resumed and that the search for the vein on the 200-ft. level is to be continued. Men who have been at the mine recently say that 40 ft. of drifting in a direction opposite to that in which the former work was done should result in the vein being entered.

YERINGTON.—Gypsum for use in the manufacture of portland cement is being shipped from the mines of the Ludwig Mines Co at a rate of 100 tons daily. Twenty-five men are employed by the cement company, which is developing the deposits under a lease which may be extended to ten years as a result of the large tonnage of material, containing 85 to 95% gypsum, that has been developed. The company is developing two deposits and has a plant at Mound House on the Southern Pacific railroad. The largest and most valuable deposit is said to be at Ludwig, near Yerington, where there is reported to be 1,000,000 tons exposed. The plant at Mound House may be moved to Ludwig, according to reports.

DEATH VALLEY JUNCTION.—The Pacific Coast Borax Co., due, it is said, to a reduced demand combined with increased freight-rates, has cut the working force at the mines and treatment plant. This is the first time in the years the company has been working in Death valley that an appreciable reduction in the number of men employed has been found necessary. Increased freight-rates also have greatly reduced the output of the Carrara Marble Co. at Carrara and the Continental Fluorspar Co. at Beatty, both of which have been shipping to Eastern points. Despite the difficulties of these and other companies there are many searching for non-metallic minerals everywhere in the southern part of the State, the inquiries coming principally from chemists in industries being established on the Pacific Coast. These men ap-

CRIPPLE CREEK AND VICINITY

parently enter the field in the desert region of southern California and work north as far as Goldfield. There appears to be a demand for diatomaceous earth, used as an absorbent and polisher; sodium sulphate, used in the manufacture of glass; barite, used to weight paper, and, as barium hydroxide, in refining sugar; fuller's earth, used in refining oil; and calcite in the form of chalk for fertilizer. Fuller's earth is being mined on a large scale at Shoshone and oil companies continue to buy ground there.

BONNIE CLARE.—The first carload of lead-silver ore from the Arrowhead Rico, at Ubehebe, California, has been loaded here and another carload is nearly ready. The ore is being shipped to the United States Smelting, Refining & Mining Co. under a contract made by J. C. Brumblay of the Salt Lake office of that company, who recently visited the mine. Work in the tunnel at a depth of 80 ft. has been stopped until the tunnel can be cleared

of broken material and this sacked and shipped. The ore-shoot has been opened for a distance of 60 ft. and the limit has not been reached.

FALLON.—The Silver Range Mines Co., operating in the Cox canyon part of the Silver range, east of Fallon, plans to spend \$100,000 in additional development work on the 52 claims owned by the company. Two veins are being developed, one copper-silver-gold and the other silver-lead-gold. The company has done 5000 ft. of development work and the present work consists of a tunnel that has been driven 50 ft. in ore two feet wide and assaying \$40 in silver and lead. It is reported that much low-grade ore has been opened and the company plans to erect a concentrator eventually.

ELY.—The Nevada Consolidated, following in the wake of other big copper companies, has announced a general reduction in wages, including a cut of \$1.25 for craftsmen, \$1 for other employees receiving \$5.25 or over, and 85c. for those receiving less than \$5.25. The company has been seriously affected by an order of the Interstate Commerce Commission suspending until April 29 the voluntary reduction in freight-rates on smelter products that the railroads granted. It is said that this order will make it difficult for the company to operate the smelter at a profit because of the low price for blister copper, which is the principal product.

VIRGINIA CITY.—The Virginia City Miners' union has voted on and accepted a wage-scale agreement for their part of the district practically identical with the agreement recently reached between the Gold Hill miners and operators. The agreement involves a gradual reduction in wages to \$4 on December 1, 1921. The vote is said to have been almost unanimous.

EUREKA.—At the Eureka-Croesus mine the 'shale' raise has holed through into the old workings and a drift has been started on the ore. In raise No. 8 the face of the shale is dipping flatter to the west; this is believed to indicate the near presence of ore. In No. 2 raise, along an east-west fracture leading from the north-south fissure, high-grade ore is being extracted, said to be identical with a similar body found in that locality a year ago. On three other cross-fissures, within 100 ft., the showing is promising. The company is adding to its holdings by purchasing contiguous ground. Development work is carried on through the Catlin shaft, at the southerly end of the Connolly claim at the most southerly part of the Eureka-Croesus property. A double-gear 60-hp. air-operated hoist and two Chicago pneumatic air-compressors of 356 cu. ft. have been received at the mine, but are not yet installed. The Eureka-Eclipse mine, just west of the Holly and Bullwhacker mines, north of Adams hill, is being developed. The company is sinking a shaft in quartz porphyry which assays from a trace to 80c. per ton and is the same formation in which the ore-bodies in the Holly and Bullwhacker occur. The shaft at the Eureka Holly mine is down to the 600-ft. level, where a station is being cut out. Sinking will be resumed as soon as the station is finished. The machinery for the

Holly mill has been hauled to the ground and is being installed.

At the Uncle Sam Con. mine a contract has been let to drive an additional 100 ft. in the main adit, which enters the property from the south side of New York canyon. The face of the adit is now 350 ft. from the north end of the Hamburg mine; within the last 10 ft. two stringers of ore, which look promising, were cut.

UTAH

FOREIGN CAPITALISTS ARE INVESTIGATING OIL-SHALE RESOURCES OF UNITAH BASIN.

SALT LAKE CITY.—Carl A. Allen, State Inspector of Coal Mines, estimates that the coal production in Utah during 1920 was 5,818,500 tons, as compared with 4,629,722 tons for the preceding year. The record output for any one month in the history of coal mining in this State was in January 1920, when 589,668 tons was mined. Had this record been maintained throughout the year, production would have been 7,076,016 tons. Mr. Allen estimates that the maximum capacity of Utah coal mines, as at present developed, working eight hours per day for 52 weeks per year and without any interruptions, from labor shortage, strikes, lack of market, mine disability, and other causes, is about 8,760,000 tons per annum.

A representative of an English syndicate, two of a Belgian company, and two of a French syndicate, operating jointly, have been in the Uintah basin inspecting the enormous deposits of oil-shale in that locality, according to R. S. Collett, of Roosevelt, Utah, who represents local capitalists interested in the deposits, said to aggregate 40,000 acres. After spending some days in the Basin, the representatives left for New York, to present their report.

The local lead-smelting companies are being seriously affected by the decline in ore shipments, owing to the unsatisfactory condition of the metal market. At the United States smelter at Midvale, W. A. Howard, manager, reports that its heaviest shipper of high-grade lead concentrate, the Snowstorm mine at Troy, Montana, has suspended operations entirely; the Pittsburg-Idaho and the Latest Out properties at Gilmore, Idaho, have also closed, as has the Utah-Apex mine at Bingham, the largest producer of lead in Utah.

BINGHAM.—During its fiscal year ending August 31, 1920, the Utah Apex Mining Co. had gross receipts of \$1,279,562, while expenses, including cost of litigation and a charge of nearly \$100,000 for depletion and depreciation, amounted to \$1,224,277, leaving net profits of \$55,285. On that date the company had current assets of \$621,535, mostly cash and Liberty bonds, against current liabilities of \$77,501. During the year various changes were effected in the flotation department of the concentrating plant, which increased its efficiency, and considerable attention was devoted to the question of a lead-zinc separation in the mill on a commercial scale. The mine, as now developed, has a capacity of 1000 tons output per day. The Utah Consolidated company is now withdraw-

ing its equipment from the territory awarded to the Utah Apex company on October 21, 1920, by the United States District Court of Utah.

EUREKA.—The directors of the Grand Central Mining Co. have declared a dividend of one cent per share, payable January 21, which will call for the payment of \$6000. A dividend of four cents per share was paid during the first quarter of 1920, and one for three cents per share during the second quarter of the year. The total of such disbursements to date is \$1,866,000. The directors of the Gold Chain Mining Co. have also declared a dividend of one cent per share.

During the week ending December 25, the Tintic Standard shipped 50 cars of ore; Chief Consolidated, 45; Dragon, 22; Eagle & Blue Bell, 13; Iron Blossom, 13;

BRITISH COLUMBIA

PROPOSED MEASURES FOR STIMULATING GOLD MINING.

VANCOUVER.—The necessity of encouraging the production of gold in British Columbia is becoming increasingly apparent; the latest public body to take action is the Mining Bureau of the Vancouver Board of Trade which recently passed a resolution offering a number of suggestions to the Dominion and Provincial governments. One is the removal of all taxation on gold mines until "such time as conditions return to normal"; another "the return to Canada of all gold produced from exported ores and the purchase thereof by the Mint at Ottawa and the Dominion Assay Office at Vancouver"; and a third "that all gold sold by the before-mentioned

SILVER STANDARD MINE NEAR HAZELTON, B. C.

Iron King, 9; Victoria, 7; Gemini, 4; Mammoth, 2; Gold Chain, 2; Colorado, 2; Swansea, 2; Tintic Drain Tunnel, 1; making a total of 172 cars, as compared with 180 for the preceding week. The decrease in shipments is due to the fact that the Tintic Standard has been requested by Salt Lake Valley smelters to hold its production down to approximately 300 tons per day.

Walter Fitch, president of the Chief Consolidated Mining Co., returned on December 24 from Washington, D. C., where he attended the meetings before the Interstate Commerce Commission on freight-rate hearings as applying to ore shipments in this State. Mr. Fitch states that he feels confident that the Interstate Commerce Commission will uphold the action of the Utah Public Utilities Commission and that there will be no increase in the present rates on coal and ore shipments. With the decreases in prices of metals, even the largest lead and silver producers in this district are operating on a comparatively small margin.

institutions for industrial purposes should be so priced as to cover the normal cost of production, any surplus revenue to be distributed among the gold-mining companies in proportion to production".

Rumors are in circulation to the effect that negotiations are in hand having in view the transfer of the holdings of the Granby Consolidated Mining & Smelting Co., Ltd., at Anyox, including the Hidden Creek mine, and at Cassidys, Vancouver Island, where is situated a modern coal-mining plant now in operation, to the Canadian Consolidated Mining & Smelting Co. It is stated, briefly, that engineers representing the Canadian Consolidated, a subsidiary corporation to the C. P. R., have been over the plant of the Granby company at Anyox; that the C. P. R. would find it convenient to have the output of the Cassidy Collieries available now that coal is replacing oil as fuel for its coast steamships and its British Columbia railways; and that the Canadian Consolidated has long been feeling its way toward the establishment of a

smelter on the coast. On the latter point reference is made to the company's expenditure of approximately half a million dollars in the development of the Old Sport mineral claims, on Quatsino sound, to its interest in the Sunloch Mining Co.'s properties; and to the option it has secured on the Big Interior group. All these are copper prospects and, if development proves them capable of producing the tonnage of copper-bearing ore now indicated, especially in respect of the Old Sport and the Sunloch, a smelter on the coast for the treatment of the ore will be necessary. Hence it is claimed to be not unlikely that the Canadian Consolidated Co. might consider the acquirement of the Granby company's holdings.

BARKERVILLE.—R. F. Ward states that he has bonded the Bullion mine to New York and Kansas City interests, and that a deposit of \$20,000 has been made to bind the deal. The consideration has not been divulged. This property has seen many vicissitudes. At one time it was owned by a group of Canadian Pacific railroad officials, including Messrs. Van Horne and Shaughnessy, who spent in the neighborhood of two and a half million dollars in exploration and the construction of canals, and who took about half a million dollars worth of gold from the property. Then it passed into the hands of the Guggenheims, who spent considerable sums in development. From the Guggenheims it passed to the present owners in 1913, and then became involved in legal complications, from which it was not freed until recently. During the six years of idleness much of the original construction work has fallen into decay, and, Mr. Ward estimates, fully a quarter of a million dollars will be required to put the property on a working basis.

TRAIL.—During the third week in December 9967 tons of ore was received at the smelter, 9168 tons coming from the Consolidated company's mines. The other shippers were: Canada Copper, Allenby, 161 tons; Horn Silver, Chepaka, 53; Josie, Rossland, 256; North Star, Kimberley, 190; and Paradise, Lake Windermere, 138. There is a considerable supply of all base metals on hand at the smelter, and all but absolutely necessary work has been stopped. This has caused the dismissal of a large number of men, and, as a consequence, curtailed expenses.

ONTARIO

MERGER OF THE VIPOND-NORTH THOMPSON AND NORTH CROWN IS PROPOSED.

PORCUPINE.—Negotiations are in progress looking to the merger of the Vipond-North Thompson and the North Crown Mines Co. As a preliminary step Major Bell, manager of the Vipond-North Thompson, has made an examination of the workings of the North Crown and H. J. Stewart, manager of the North Crown has investigated the records of the Vipond-North Thompson, the mine being inaccessible owing to its being full of water. A meeting will be held this week in Montreal for the purpose of arriving at a basis of amalgamation. The combined area embraced in the proposal is 320 acres. Each of the two groups has a mill with a capacity of 120

tons per day. It is estimated that important economies in operating costs can be effected by the amalgamation, as the ore in the mines involved often extends from one property into another, and one of the improvements likely to be carried out should the merger take place will be the utilization of the North Thompson shaft as a main hoisting-way for the combined properties. On the Krist property of the North Crown diamond-drilling almost horizontally from the 500-ft. level has passed through several important orebodies. About 250 ft. of cross-cutting has been undertaken in order to reach them.

The Hollinger Consolidated by the use of auxiliary steam equipment has been able considerably to increase its tonnage, having treated as much as 2400 tons of ore in 24 hours, as compared with an average of between 1700 and 1800 tons during November.

KIRKLAND LAKE.—During November the Lake Shore treated 1810 tons of ore with a recovery of \$49,339 being an average production of \$27.25 per ton. Production during the company's fiscal year which ended November 30 was \$483,701, the average recovery being \$25.63 per ton. More than half the ore treated came from development work, otherwise a much higher average would have been reported.

Operations at the Teck-Hughes have been temporarily suspended on account of a broken hoist, which is expected to be repaired in about a week.

COBALT.—As the result of a conference between representatives of the Workmen's Central Council and the Temiskaming Mine Managers Association it has been decided to hold the proposed sick benefit scheme in abeyance. The reason assigned is that under the unfavorable and uncertain conditions now prevailing it would be unwise to start at present, as the comparatively small number of men now employed would not provide sufficient funds to fairly test the feasibility of the scheme. It was decided to postpone its operation till some future date, probably May 1.

A new company has been organized under the name of the Ruby Co-operative Cobalt Mines, Ltd., with a capitalization of \$1,500,000, to take over and operate the Ruby mine in the south-eastern part of the Bucke township. Development during the fall has met with encouraging results and a considerable quantity of good milling ore has been opened.

Much importance is attached to the deep drilling operations now being carried on at the Crown Reserve mine. The hole that is being put down to test the ground underlying the diabase in the section where the principal veins have been found is now down 1300 ft. below the surface. Officials of the Dominion Geological Survey are making a study of the geology of the mine as shown by the drill.

LARDER LAKE.—The Crown Reserve plans to carry on exploration of its claims by diamond-drilling beginning early in the year. Exploration of a belt running north from the Costello claims was undertaken during the summer but little progress was made by reason of the heavy overburden. In places where they did get through the results were encouraging.

THE MINING SUMMARY

CALIFORNIA

Calaveras County.—The new 10-stamp addition to the mill of the Carson Hill Co. has been in operation about a month, bringing the total capacity of the plant up to 500 tons of ore per day. The ore is reported to average about \$11 per ton, with total operating expenses ranging around \$4 per ton. The company is at present developing an extensive area of ground adjacent to its productive territory and steadily increasing the reserves of commercial ore. Plans for 1921 include opening new levels, exploration of new sections of the outside territory, and maintenance of capacity production.

Nevada County.—Unwatering of the inclined section of the main shaft of the Idaho-Maryland mine has reached a point where the company will soon be in a position to undertake exploration of the lower levels. In the upper levels, served by the vertical part of the shaft, lessees have opened shoots of profitable ore, but the chief interest centres on prospective discoveries in the lower workings. The mill is running on ore from leasing operations, and the shaft is being unwatered as rapidly as practicable. The enterprise is managed by the Bulkeley Wells Syndicate and ranks among the most important in the Grass Valley district.

Sierra County.—Temporary suspension of mining at the Kate Hardy property has been ordered and most of the miners have been laid off. The reason given is the inability of the company to finish its reduction plant as soon as expected and the lack of further storage space for ore. Work on the mill is being rushed as fast as weather conditions will permit. The shaft is now sunk to a depth of nearly 200 ft. At the 100-ft. level a station has been cut and a large centrifugal pump installed to handle the water. Another station is to be cut at the 200-ft. level, and drifts will be run both north and south on the vein.

COLORADO

Cripple Creek.—Gold production from the mines of the district, due to prevailing labor conditions and high operating costs for the year 1920, is the lowest since 1895, when the camp, but five years old, produced \$6,100,000. The 1920 total is reported at \$5,956,222. The production by months was as follows: January, \$609,674; February, \$511,500; March, \$605,000; April, \$473,590; May, \$442,867; June, \$494,264; July, \$614,937; August, \$477,603; September, \$426,489; October, \$425,298; November, \$450,000; and December, \$470,000.

IDAHO

Coeur d'Alene.—That the Bunker Hill & Sullivan company will erect a million-dollar electrolytic-zinc refinery at Kellogg, and that through the purchase of an interest in the Northwest Lead Co., of Seattle, it has entered into the manufacture of lead plumbing material, has been announced by Frank M. Smith, smelter director of the Bunker Hill & Sullivan company. "The company has definitely decided to go into the zinc field," said Mr. Smith. "An electrolytic-zinc plant is to be built at Kellogg to treat the Star ores, probably using this process. We are making arrangements with the owners of the Star mine that, when market conditions are favorable, the mine will be operated and the ores

treated at the Bunker Hill & Sullivan plant. The ore is a complex zinc-lead ore from which two concentrates will be made: lead, which will be treated at the smelter; and zinc, which will be handled by the proposed new electrolytic plant. The initial capacity will be 25 tons of metallic zinc per day, so arranged that the capacity can be increased to 50 tons per day when market conditions warrant. The plant will cost approximately \$1,000,000 for the first unit. We are going ahead with the plans so that they will be in readiness for use as early as next year if building costs justify. It will be two years probably before the plant is in operation. The Bunker Hill & Sullivan company has bought a substantial interest in the Northwestern Lead Co., of Seattle, a concern manufacturing lead pipe, sheet-lead, lead traps, bends, and many other lead products for the plumbing trade. This company has been operating for the last two or three years and has used the Bunker Hill & Sullivan pig-lead exclusively. Now that the Bunker Hill & Sullivan company has acquired a financial interest in the company, it is proposed to extend its market in the north-west territory."—The Morning Club, of Mullan, was recently dedicated. It is evidence of broad-minded policies on the part of the Federal Mining & Smelting Co. The expenditure of \$100,000 for the club-house and its equipment is the indirect result of prohibition, which left the miners without their usual recreation resorts. The company, which owns the Morning mine, felt that something should be done to make pleasant the leisure hours of its men. They planned the club-house, first intending it to be built at the mine. Citizens of Mullan asked the company to put the club at Mullan and the citizens of Mullan furnished the site. Everything else, including entire furnishings and equipment, was paid for by the mining company. Mullan people are given the privilege of the club.—The Idaho Mines Leasing Co. has secured good results in exploring the old Black Bear mine on Canyon creek. It has ordered a 50-ton mill which it is building and which it expects to have ready for operation by January 1. This is the Black Bear belonging to the old Frisco mine and now held by the Federal Mining & Smelting Co. The Idaho Leasing Co. has a lease on all the workings of the Black Bear above the No. 3 tunnel. A good body of lead-silver ore has been discovered which is said to be four feet wide and 200 ft. long. The lessees say they have enough ore in sight to operate their mill for three years. Bins have been built at the railroad and an 800-ft. cable tram installed from the bins to the tunnel above that will be used in bringing out the ore.—Material for the new concentrator at the Yankee Boy mine on Big creek of the Coeur d'Alene is now being delivered at the property. The Yankee Boy property was recently consolidated with the Sunshine Mining Co.'s holdings and will be operated by that company. The property has been a shipper of high-grade silver ore for a number of years, shipping a hand-sorted product, in the course of which a large tonnage of mill-ore has been accumulated. This will now be treated in the new mill, which also treats the lower-grade ore taken from the mine while extracting the richer ore.—Steady development of the Chicago-Boston mine is proceeding. In the lower tunnel at a point 420 ft. from the shaft a cross-cut has been started and run 50 ft. south-easterly. This is intended to cut into

the orebody found on the 200-ft. level.—The Paragon mine in the Murray district expects to sink its shaft to an additional depth of 300 ft. The company's mill has been overhauled and is in better shape now than ever before. The additional depth will give a much better grade of ore than that which was shipped some years ago from the upper levels of the property.—The Giant Ledge Mining Co. will continue work throughout the winter and by spring hopes the development work will warrant completing and operating the mill which is partly constructed. From the bottom of the 400-ft. shaft the vein has been followed 900 ft., and at no point in that distance is the tunnel out of ore, although at some points its grade was not as good as at others. The vein is 35 ft. wide at the far end of the tunnel.

Soda Springs.—The construction of an eight-mile branch by the Union Pacific Railroad Co. from Soda Springs to the phosphate mines of the Anaconda Copper Co. has been completed, together with the 'y's' for loading-purposes, and two locomotives are on the ground and power connections for 4000 horse-power have been made with the lines of the Utah Power & Light Co. At this property Anaconda has a working supply of phosphate ample for 100 years, according to engineering estimates, the indicated tonnage amounting to about 200,000,000, with ample phosphoric acid content. The company also has on the ground a 'mucking' machine which will handle ten tons of rock at a shovel. Plans are under way for the shipment of approximately 1000 tons of phosphate rock daily to the Washoe smelter, where it will be treated with sulphuric acid, the latter manufactured by a special process devised at the Anaconda smelter.

MONTANA

Butte.—Metal production of the Anaconda Copper Co. at present is approximately 38% of normal based on an output of 10,000,000 lb. monthly as compared with 26,000,000 lb. for the same period a year ago. The latter amount is regarded as a fair average of the capabilities of the Anaconda company. But the ore output is considerably less, as included in the metal production is the copper obtained from the treatment of accumulated tailings at the Washoe works. The company has increased the number of its lead-stacks at the Boston & Montana smelting works at Great Falls from one to three. The residue from the electrolytic zinc-plant is being treated for its lead content. Heretofore this residue was shipped to the Tooele smelter of the International company in Utah, which is controlled by Anaconda, but the increased freight-rates forced Anaconda to more economical measures. This is the first lead-smelting operation which the company has conducted in Montana. Following the announcement of the reduction in wages, John Gillie, manager of mines for the Anaconda company, said: "Under present conditions every pound of copper and zinc mined in the Butte district is produced at a loss. There has been no market for the metal and with enormous surplus of copper and zinc in the country and the low price of the metal an adjustment of operations to suit present conditions became imperative."

East Butte is hoisting around 300 tons of ore daily of a grade exceeding 5% copper. Underground sorting is done efficiently at the Pittsmont mine of the company and in consequence the management has been able to make a good showing as far as the grade of ore is concerned. Underground sorting is not employed generally in the Butte district, but is advantageously done when extra economy of operation is necessary. East Butte is employing 140 men at the mine and about 75 in its smelter, where it treats the ore from Davis-Daly, which amounts to from two to three cars daily, averaging 50 tons each.

Cooke City.—The Republic, Glengarry, and Irma mines are producing some good ore. The ore is being hauled by truck to Gardiner, where it is loaded for shipment to the East Helena smelter.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Willard S. Morse is at Los Angeles.

C. Erb Wuensch, of Denver, is here.

B. L. Thane has returned from Los Angeles.

Nelson Dickerman has sailed for Japan and China.

A. H. Bedford, recently at Grass Valley, has gone to New Zealand.

Oliver C. Ralston, of the U. S. Bureau of Mines, is in San Francisco.

E. A. H. Tays, recently of Sinaloa, Mexico, has moved to Nogales, Arizona.

Robert Bulman has arrived in San Francisco from Reef-ton, New Zealand.

Courtenay De Kalb has been to Bagalusa, in Louisiana. He is now at New Orleans.

D. J. Argall, of San Diego, California, has gone to Thane, Alaska, in care of the Perseverance mine.

H. C. Goodrich, chief engineer for the Utah Copper Co., spent several days at Los Angeles recently.

L. W. Storm, of Seattle, is examining the old placer mines of Sonora, in Tuolumne county, California.

John T. Reid, mining engineer of Lovelock, Nevada, has gone to New York, expecting to return in May.

P. A. Simon, president of the Simon Silver-Lead Mines Co., at Mina, Nevada, was in San Francisco this week.

H. V. Burgard, secretary for the Mineral Metal & By-Products Co. of Denver, has returned to San Francisco.

H. G. Thiele is superintendent of the Borosolvay potash plant of the Solvay Process Co., at Borosolvay, California.

S. M. Soupcoff, mining engineer with the Utah Department of the A. S. & R. Co., is making an extended visit in the East.

T. L. Josephs, metallurgist with the U. S. Bureau of Mines at Minneapolis, has been examining coal and iron deposits in the vicinity of Cedar City, Utah.

Oscar Friendly, superintendent of the Judge properties at Park City, Utah, has returned home after a trip to St. Louis and the mining districts of Missouri and Colorado.

C. Minot Weld, **Donald M. Liddell**, and **Paul H. Lazenby** announce that they have formed a partnership for practice as consulting engineers and economists at 2 Rector street, New York City.

D. H. Bradley Jr., who was manager for the Parral Consolidated Mines Co., at Parral, Mexico, has recently been released from his commission in the Army and is in San Francisco.

E. L. Jorgensen, formerly general superintendent of reduction with the Chile Exploration Co., at Chuquicamata, has after 15 years with the Guggenheims opened an office as consulting engineer at 150 Nassau street, New York.

W. R. Crane is now superintendent of the Bureau of Mines Experiment Station at Tuscaloosa, Alabama, with headquarters at Birmingham. Mr. Crane has been chief engineer for the War Minerals Relief Commission at Washington during the past year.

Joseph H. Brown, assistant purchasing agent for the Ray Consolidated Copper Co. at Hayden, Arizona, died on December 29. For a number of years he was general storekeeper for the Denver & Rio Grande Railroad at Salt Lake City. About 15 years ago he became purchasing agent for the Boston Consolidated Mining Co., and when that company was taken over by the Utah Copper Co. early in 1910, he went to Arizona and has been connected with the Ray Consolidated since that time.

THE METAL MARKET

METAL PRICES

San Francisco, January 4

Aluminum-dust, cents per pound	65
Antimony, cents per pound	9.50
Copper, electrolytic, cents per pound	14.00—14.50
Lead, pig, cents per pound	5—6
Platinum, pure, per ounce	\$75
Platinum, 10% Iridium, per ounce	\$115
Quicksilver, per flask of 75 lb.	\$50
Spelter, cents per pound	8.25
Zinc-dust, cents per pound	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

January 3.—Copper is quiet and steady. Lead is more active and stronger. Zinc is quiet and higher.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

WHOLESALE COMMODITY PRICES

Below are shown quotations as of December 15, 1920, for those commodities regularly carried in 'Commerce Monthly', together with the highest price for the fifteenth of any month since the armistice. Prices of specific commodities which were under government control are compared with the highest price recorded after the removal of control.

It should be specifically noted that the price for the nearest available date to the fifteenth of each month was not necessarily the highest price reached. For purposes of comparison, the price is also shown for January 15, 1914.

Commodity, unit	Date	Price	Highest price for 15th of any month since armistice or since removal of government control	Price on 15th of Dec. 1920	Jan. 1914

MONEY AND EXCHANGE

Foreign quotations on January 4 are as follows:

Sterling, dollars: Cable	3.56 1/4
" Demand	3.57 1/4
Francs, cents: Cable	5.88
" Demand	5.88
Lire, cents: Demand	3.45
Marks, cents	1.41

Eastern Metal Market

New York, December 29, 1920.

The year draws to a close with the demand for all metals almost nothing and with prices practically readjusted to pre-war levels. They are also at the lowest levels for the year, the declines having come in the last three months.

There is almost no buying of copper and prices are a little lower.

Consumers and dealers remain absent from the tin market and quotations are nominal.

Only a very moderate demand exists for lead and prices are a little easier.

The zinc market is lower because of weakness in London. Antimony has declined.

IRON AND STEEL

In taking account of conditions as the new year comes in, the iron and steel trade sees no prospect of a buying spurt for some weeks. The flood of shipments from mills of accumulated and current output following the release of cars restricted up to that time to carrying coal, has placed in large consumers' yards somewhat more material than they were able to dispose of, especially with the curtailment in general demand.

The last week of the year is marked by production at full blast by the Steel Corporation and by total idleness of some independent plants and for others rates varying up to perhaps 55%, or an average of about 25% for the independents and not much over 54% for all the mills. Revision of steel contracts to the basis of March 1919 has not prevented suspensions, and in the case of the Steel Corporation the successive suspensions since August have been released only in a small measure, and it seems clear that the leading producer has now less than six months orders, particularly in view of its present high scale of operations.

COPPER

What little business is reported is for small lots for prompt delivery and this is being taken largely by small interests at concessions or by those needing cash. The volume is negligible and it may be said that the market is stagnant. Quotations, largely nominal, are 13.25 to 13.50c., New York, for electrolytic copper for prompt and early delivery, with 13.50 and 13.75c. asked for first quarter. Large producers either have no price or ask 14c. for prompt and future. Production is being curtailed, but to what extent is mere conjecture.

A study of recent statistics shows surprising imports of refined and old copper. To November 1, 1920, receipts of refined copper have been 98,745,714 lb., against 35,138,760 lb. in all of 1919. Of old copper, classed as 'old and clippings', the imports for the first 10 months of 1920 were 9,742,907 lb. or at a monthly rate three-fold greater than in 1919 and 50% heavier than in 1913. Even old brass receipts are very heavy, having been 34,864,700 lb. to November 1, 1920, or three times what they were in all of 1919 and nearly four times the 1913 imports.

TIN

There is little life to the market and quotations are largely nominal. Consumers, dealers, and even speculators show no interest and until they do no betterment is possible. There are expressions to the effect that an active tin market will be witnessed early in 1921, but this will depend on the attitude of consumers, the market at present being stagnant. It is in fact so lifeless that a measure of values is difficult. The week has brought forth almost no sales, the only one reported having been 50 tons of January shipment Straits, sold on the New York Metal Exchange on December 23 at

32.75c. Spot Straits tin, New York, was quoted yesterday at 33.50c. nominal. The London market, closed Monday and Friday, was low yesterday at £200 per ton for spot standard, £205 15s. for future standard, and £205 for spot Straits. Arrivals thus far this month have been 2420 tons, of which 180 tons is credited to Pacific ports with 1890 tons reported afloat.

LEAD

Some sellers are of the opinion that the bottom of the market has been reached this time at 4.50c., St. Louis, for outside market, and 4.75c., St. Louis, for the leading interest. There are a few sellers who sold on the decline and are not as eager for new business and there are others who do not want to compete at present levels, with the result that there are less sellers than a week or so ago. This makes for a steadier stronger market tone. A little more interest is reported in small lots of one to three carloads, but actual business is small. We quote the outside market at 4.45 to 4.55c., St. Louis and New York, the latter being influenced by possible or actual imports.

ZINC

The London position is the dominating factor in the American market. New levels for the year have been made in London, where prime Western has fallen under £24 per ton, against £50 some months ago. While the British market was £1 higher yesterday than last week, already sales of about 2000 tons have been made for importation into this country in January and February at around 5.40c., seaboard, duty paid. This tendency had lowered the American market to 5.50c., St. Louis, on Monday and to 5.60c. yesterday, with the New York price for imported metal at practically the same figure, 5.65c., New York. Domestic metal for delivery in the East is around 6.10c. All quotations are for prompt delivery, producers not being willing to sell futures and selling only for immediate requirements.

It is authoritatively estimated that Belgian zinc cannot be produced under £40 per ton, while German zinc can be made around 1 to 1.50c. per pound, but in limited quantities for export. This is taken to indicate a good future for American zinc.

ANTIMONY

Wholesale lots for early delivery are obtainable at 5.25c., New York, duty paid. There is no demand.

ALUMINUM

Virgin metal, 98 to 99% pure, is obtainable from independent sellers at 22 to 23c. per pound, New York, while the quotation of the leading interest is 28.30c. f.o.b. producer's plant for 15-ton lots for early delivery.

ORES

Tungsten: There has been a light business in small lots. Predominant in the minds of the trade is the tariff bill and the effect on the tungsten industry. As low as \$3.50 per unit could now probably be done on low-grade ore, with other grades proportionately higher.

Ferro-tungsten can be obtained as low as 59c. per pound of contained tungsten.

Molybdenum: The market is devoid of feature or interest. No test of values is reported.

Manganese: No business has developed and prices for high-grade ore are nominal at 35 to 40c. per unit, seaboard.

Manganese-Iron Alloys: British ferro-manganese from at least one producer can be obtained at low as \$110, seaboard, on a firm offer. American makers will probably meet any British price when business is offered. At present demand is almost nil. Spiegeleisen can be obtained as low as \$45, furnace, and perhaps lower. A sale of 200 tons is noted.

		INDUSTRIAL PROGRESS

The age-old dream of the alchemist is realized because of Linde

THROUGH countless centuries man dreamed of transmuting the baser metals into gold. Patiently, laboriously, often consecrating their very lives to the work, the Alchemists of old toiled on toward their elusive goal.

As late as 1873 James Price, the last of the Alchemists, sought death by his own hand rather than acknowledge the failure of his experiments.

Linde Engineers of to-day have made this dream of by-gone ages come true.

By producing uniformly pure oxygen in industrial volume, they have made it possible for oxy-acetylene welders and cutters to reclaim thousands of tons of metal machinery annually—turning base metal into gold—a saving in money far in excess of any vision of wealth dreamed of by ancient philosophers.

And Linde does more than supply oxygen of absolutely uniform purity. Thanks to a chain of twenty-nine plants and forty-six warehouses it delivers Linde Oxygen when and where it is wanted in any volume.

THE LARGEST PRODUCER OF OXYGEN IN THE WORLD

T. A. RICKARD, . . . Editor

WE have received an interesting letter, postmarked Paxton, California, on the Eilers v. Guggenheim affair, but, unfortunately, it is anonymous, and therefore cannot be published. If the gentleman will disclose his identity, not necessarily for publication, but for the Editor's information, his letter will be published.

QUESTIONS continue to come to us asking whether a locator must make a declaration or take any other steps in order to avail himself of the extension of time for doing assessment work on a mining claim. As we understand the recent enactment of Congress, he need not do so; if he does his \$100 worth of work before July 1 his rights will be maintained as if the work had been done before December 31, 1920.

C. W. Barron of the 'Boston News Bureau' has a good deal to say on current events and most of it is to the point. He has a way of speaking plainly that we like, because it saves time and thinking. Our present ills, he says, are due to the fact that "it was deemed patriotic, good politics, and good business to double wages to produce for the War. It is now seen as bad business, bad politics, and most unpatriotic." The luxurious wages have destroyed thrift as well as efficiency. We camouflaged the wage-profiteers who did a third of a shift for \$10 by calling them our base-line of defence. Retail prices were advanced, by the greed of the middlemen, until the workers with doubled wages were no better off than before. Now comes the reckoning: the bromo-seltzer after the jag! It remains for us as a nation to devise simpler forms of taxation, to curtail the expense of government, to unshackle enterprise, and to cultivate habits of thrift.

ZINC OXIDE is being made from sulphide concentrate in a single furnace-operation at the plant of the Metals Extraction Company at Joplin. Mr. Charles E. Schwarz, manager of the plant, developed the process, which consists essentially in burning a mixture of unroasted concentrate and pulverized coal under a strong forced draft, the sulphur in the ore supplying part of the fuel to promote combustion. The entire cycle of treatment requires but 45 minutes, and is conducted alternately in each of a pair of twin furnaces, the oxide being collected in a bag-house in the usual way. De-

tailed technical information as to the construction of the furnaces, the fineness of the concentrate and fuel, the proportions used, the extraction obtained, and the purity of the resulting product are not at hand, but sufficient success has been attained to warrant thorough investigation by representatives of large companies with the expectation of making use of the process. There is a long stride between metallurgical accomplishment and the successful application of the scheme on a commercial basis with resultant economy in the production of a satisfactory grade of zinc oxide, but apparently progress has been made.

IN this issue we publish a description of the Greenawalt machine by the brother of the inventor, Mr. John E. Greenawalt. Mechanical furnaces for desulphurizing concentrates or other fine mill-products and at the same time producing a 'cinder' suitable for treatment in the blast-furnace have made notable progress in recent years. The Dwight-Lloyd machine, for example, forms a prominent feature of the new Bunker Hill smelter and details of the construction and operation of this well-known sintering furnace were given in the article appearing in our last issue. The Greenawalt machine is not as well known, but is being used on a large scale, notably by the Bethlehem Steel Company, at Lebanon, Pennsylvania, where one 1000-ton machine is in operation and a second will soon be ready to start, taking the place of several nodulizing furnaces. At Duquesne, also in Pennsylvania, the U. S. Steel Corporation is erecting a second Greenawalt unit of 1000 tons, for the purpose of treating the current product of flue-dust. We are informed, by Mr. William E. Greenawalt, that the wider use of his brother's invention has been delayed by patent litigation. The novel idea is said to be the porous or permeable bed of non-sinterable material underlying the charge; this preserves the grate and simplifies the discharge of the sinter. We understand that the litigation with the owners of the Dwight-Lloyd patents has been adjusted satisfactorily to all concerned.

MOST of us like to give both sides a chance. That is why we publish an article in defence of Minerals Separation. It consists of portions of a speech delivered by Mr. Alfred A. Cook, counsel for Minerals Separation, in Denver before the Flotation Conference of the American Mining Congress. We give about half of the speech

as sent to us by Mr. Cook himself, regretting that the exigencies of space prevent us from giving it all. His opponents, Messrs. Nye and Montague, had the advantage of him, in that their statements were prepared and written, whereas his was impromptu and delivered as a speech; therefore it is diffuse and repetitive, as oral utterances usually are, but it has a pleasant naturalness and a personal touch that a written statement lacks. In selecting extracts for publication, we have used our own judgment, giving our readers those that seemed best to express the speaker's ideas—that is, we have selected what we think he would have wished to be published, if compelled to apply the Procrustean method. Our readers will be interested in the speech; they have read our own attacks often and they will have wondered if there were any defence and what the nature of it might be. We are glad to give them Mr. Cook's speech, knowing him to be a shrewd and courteous antagonist.

ON January 1 the Engineering Council, formed in 1917, was formally merged in the American Engineering Council of the Federated American Engineering Societies, of which Mr. H. C. Hoover is president. The four vice-presidents are Messrs. Calvert Townley, William E. Rolfe, Dexter S. Kimball, and J. Parke Channing. To Mr. Channing the Engineering Council is largely indebted for its success, and it is the good work that it has done that has led to the formation of the larger and more comprehensive organization. It is announced in New York that "the new council will enter immediately upon a campaign of public service and will cooperate with chambers of commerce, labor organizations, and other bodies in an effort to solve pressing social, industrial, and political problems". Efficiency and economy in government is one of these important subjects, and more particularly the reorganization of the Department of the Interior as a National Department of Public Works. Mr. Channing has made public a letter received by him from President-elect Harding stating his entire approval of the plan for "bringing together under one department all the present agencies of public works now scattered around Washington". The governmental activities of the Council will be in charge of a Committee on Public Affairs, of which Mr. Channing is chairman. The Council, "whose sole idea", says Mr. Hoover, "is public service", represents nearly a hundred engineering societies, comprising more than 150,000 members. It is under excellent leadership and should do good work for the profession and the nation.

The Vanderlip Concession

If Mr. Washington Baker Vanderlip wanted notoriety, he has obtained lots of it since his return from Russia; indeed if fame be, as has been said, "getting one's name mis-spelled in the newspapers", he is even famous, for he has been called by the press Washington D. and even Frank A. Vanderlip. A nice question arises: he is described as a "well known" and "prominent" American mining engineer, and yet he is not a member of the

American Institute of Mining and Metallurgical Engineers, which is the national organization of our profession. Of course, one can be a mining engineer, even "well known" and "prominent", and yet not be a member of the Institute, but such a condition of affairs is exceptional. Sometimes an engineer quarrels with the powers that be; a paper of his is declined by the secretary of the Institute or whoever is responsible; he may have suffered some slight, real or fancied; he may dislike somebody prominent in the organization; indeed, there is ample opportunity for the play of pique or prejudice, reasonable or unreasonable, so that there are today, as always, a few engineers conspicuous by their detachment from the national organization. But they are few, and most of them are what we call 'cranks'; therefore if a mining engineer is not a member of the Institute, it is fair to say that he is not in good standing as an "American mining engineer", just as a lawyer is not in good standing if he be not a member of the Bar Association. On the face of it, that is Mr. Vanderlip's status; but in so far as he has done the work of mining engineering, notably the examining of mines and mining districts, he cannot be denied the appellation of "mining engineer". If one were to be meticulous, apropos of the Russian concession, one might prefer to call him a 'mining man', a term that covers all those engaged in making money out of mining. It is not necessary to be a mining engineer in order to do that, effectively and honorably. Our multifarious industry makes a call upon an extraordinary variety of skill, character, and experience. Mr. Vanderlip has shown unquestionable abilities of a certain, and useful, kind. He obtained what he wanted, and under conditions calling for the exercise of initiative and ingenuity of no common order. In his interview with the 'Los Angeles Times' of December 19 he gives more information concerning the Bolshevik government than Mr. H. G. Wells did in his series of articles in the 'New York Times'. Certainly he had a longer contact with Nicolai Lenin and is able to tell us more about him and his aims than the celebrated English writer. According to Mr. Vanderlip, it is acknowledged by Lenin that communism has proved a tragic and costly failure. He (Vanderlip) claims that on the concession granted to him in Eastern Siberia, no soviet or communistic laws are to apply, and he is free to employ any kind of labor he pleases. One wonders what is Lenin's purpose. Is it to embroil the United States with Japan? Is it to cause the British government to hasten recognition of the *de facto* government of Russia? Here it is interesting to note that an English court has decided that the ownership of loot does not pass to the present possessor. In 1918 the Soviet government confiscated some timber belonging to a Russian firm, and in August last the Soviet's commercial agent, Krasin, contracted for the sale of this timber to an English firm. As soon as a part of it arrived in England, the Russian owners brought suit in the English courts to establish their claim to the property, and the Court decided in their favor. As the 'Weekly Review', from which we get these facts, says, the main object of

the Krasin mission and of Bolshevik agitation for the resumption of trade is to obtain recognition of the Soviet government, thereby legalizing seizures and confiscations, and the means adopted to realize on them. Perhaps the concession to Mr. Vanderlip is meant to serve the same purpose; in any event, according to his own story, the idea is to promote a resumption of trade between the United States and Russia, and that is laudable enough, if it can be done to mutual advantage, which is the essence of all good business. Whether Messrs. Lenin and Vanderlip can give adequate assurance for the safety of business under existing conditions, is then the vital question. It remains to note the fact that even Russian gold in the form of bullion has no legal value in the United States, because our Government refuses to buy or convert any gold of Soviet origin, the reason being, as stated by Mr. Raymond T. Baker, the Director of the Mint, that its ownership is under a cloud. Agents of the Soviet government and others have been endeavoring to obtain an assurance that the ban will be lifted, but without success. The Treasury Department is standing firmly on its decision. It would appear as if the same embargo would apply to other Russian exports and that Mr. Vanderlip's concession may prove a barren coup. We have no wish that it may; on the contrary, we would like to see a resumption of trade with Russia, and more particularly the mining regions of Siberia. Perhaps the incoming administration of the new President may be able to arrange matters to that end. We have no quarrel with the Russian people, even if we consider Lenin and his friends as pirates *in excelsis*.

Power Projects

Mine operators in sundry districts in Arizona, Utah, Colorado, and Nevada, the executives of railroad companies, and others engaged in industries requiring an economical source of power will be keenly interested in the projects now under way to utilize the immense reservoir of potential energy available in the Colorado river. With its tributaries this river forms one of the largest of our drainage systems, for, according to the estimate of conservative engineers, there is available for development some 3,000,000 horse-power, equal to more than one-third the total hydro-electric power generated in the United States today. We have windmills that serve a useful purpose; a motor actuated by ocean waves has been made, though a practical device has not been perfected; and there is a reasonable chance that the tide may some day be harnessed so as to translate its energy into mechanical form suitable for running railroads and industrial plants; but at the present time there are only two important primary sources of energy, namely, that of fuel, including gas, coal, and oil, and that of falling water as developed from rivers and torrential streams. Only about 12% of the available water-power in the Western States has been exploited. The stimulation of effort in this direction was the principal purpose for the establishment about a year ago of the Federal Power Commission, which is composed of the Secretary of the

Interior and the Secretaries of War and of Agriculture. This board has recently accepted the application of the Southern California Edison Company for a permit to exploit a number of the possible water-power projects on the Colorado river, principally in Arizona. This acceptance need not be followed necessarily by the issuance of the permit; it merely establishes priority on behalf of the Edison company for a limited time, so that competing corporations cannot interfere or take advantage of the costly preliminary work that the Edison company plans to perform. The company owns a number of hydro-electric and steam plants for generating electric power and has an extensive system of distributing mains centring around Los Angeles. It is presumed to be affiliated with the Electric Bond & Share Company, a huge holding corporation in New York, with practically unlimited financial backing. It is proposed first to undertake the development of some 410,000 horse-power in Marble canyon, extending for a distance of 60 miles just below the Utah-Arizona state-line and immediately above the Grand Canyon. Here a fall of 550 ft. can be utilized to develop 410,000 brake horse-power following the construction of three dams and appropriate storage reservoirs, according to the estimates of Mr. E. C. La Rue, who made an investigation of various phases of the utilization of the waters of the river for the U. S. Geological Survey in 1916. The flow of the Colorado is peculiar; the normal minimum in Marble canyon is 3500 second-feet, while the maximum is perhaps not less than 200,000 during flood-time. To obtain the maximum amount of power it would be necessary to control this flow by storage of the water so as to permit a steady average of about 10,000 second-feet. The construction of the necessary dams is a huge undertaking, requiring a large investment; indeed, the initial cost of a hydro-electric plant and the interest on the capital constitute the chief items of expense, for the costs of operation and maintenance are comparatively small. The problem of financing the Colorado River project is affected favorably by the possibilities of reclaiming additional areas of arid land by means of irrigation. The low minimum flow seriously limits the amount of land that is now being supplied in the Imperial Valley region and in Arizona under the Laguna canal, and accordingly the plan to regulate the flow doubtless will be favorably regarded by farmers in the lower portions of California and Arizona as well as by those owners of land farther up the river who will benefit by the construction of new dams in their vicinity. The income derived from the distribution of water for irrigation manifestly lightens the burden on the users of power, and, as the area of excellent irrigable land is far in excess of the 3,000,000 acres that can be supplied, the field is an attractive one for the power companies, from that point of view. A highly important consideration affecting the success of further projects is the policy to be pursued by the railroads in the electrification of their lines. There are seven important railroads whose lines traverse the territory that may be served by power generated from the Colorado. The Chicago, Milwaukee &

St. Paul has demonstrated to its entire satisfaction, we understand, the technical efficiency of electric locomotives when operating on the mountain divisions of its transcontinental line. From the standpoint of national economies there is nothing more inconsistent than to travel up a mountain valley behind a straining locomotive that is burning tons of precious coal or oil, while at the same time one can look down at a rushing mountain stream that, day and night, is wasting the energy that might easily be employed to pull the train. A dam, a water wheel, an electric generator, and a system of copper wires are all that is needed to utilize the water and conserve our fuel. For years the Government has talked, and considered, and vacillated, but at last there is reason to believe that a method has been provided whereby the companies engaged in the power business can exploit our hydro-electric resources with some assurance of reasonable and sympathetic governmental protection. The Colorado is among the largest, but it is only one of many streams that may be utilized in a similar way.

'The Cost of Mining'

Elsewhere in this issue we publish a review of the new edition of Mr. James H. Finlay's book on 'The Cost of Mining'. This is one of the notable contributions to the technology of mining; with Mr. H. C. Hoover's 'Principles of Mining' it ranks as the most important contribution to the subject from members of the American mining profession; indeed, the fact that these two books were written by engineers of wide experience and high reputation is one of the reasons for their general acceptance as authoritative treatises. It may be ungracious to say so, but both books would have gained by more careful revision and closer editing, such, for example, as Dr. Raymond could have given to them. Unfortunately while modern books gain in timeliness and freshness by being written quickly and printed promptly, without the deliberation and delay usual in days gone-by when a disquisition on a progressive science or a growing industry was largely out of date by the time it saw the light, yet it is a pity that so many books nowadays are issued in such a hurry as to render careful revision and editing impracticable. Presumably most men prefer a book that lacks finish but is timely to one that is finished but belated, somewhere between the extremes, however, it is possible to obtain a satisfactory compromise. We make the criticism with the idea of being helpful, not of belittling the two books mentioned, which it seems to us were and are of such persistent value that they deserved more care in preparation and in printing than has been given to them. The third edition of 'The Cost of Mining' has been enriched by the addition of matter dealing with the broader aspects of the economics of mining, reflecting the author's maturer outlook. Mr. Finlay has had an experience fitting him exceptionally for the writing of such a treatise. We remember when he wrote his first contribution on the subject, in 1903, while superintendent of the Portland mine, at Cripple Creek. It was a letter on local conditions, in the course of which he

stressed the point that it was the profit, not the cost, that was the decisive factor in mining operations. That letter caught the appreciative attention of the present writer, at that time the editor of the publication to which Mr. Finlay addressed himself, and elicited a prompt response inviting him to write further on the subject. Mr. Finlay is an engineer possessing the useful faculty of mental concentration; he is able to apply himself intently on a given subject, as he has proved on several occasions since then, for instance, in his report upon the taxation of the Michigan copper mines and in his various later papers on mine valuation. In the course of his career he has examined many of the most important mines of the West; for example, the United Verde Extension, concerning which, and its geology, he gives, in this edition of his book, much information illustrating the proper method of mine appraisal. It is this foundation of professional practice that gives strength to his writing on the economics of mining; the personal contact with actualities renders his statements convincing to his readers. American technology has gained greatly by recruiting its authors from the ranks of the active profession, instead of being dependent, as was and is still the custom in Europe, upon the academic writings of indoor students of the subject. The engineer who has been outdoors, in the most expansive meaning of the word, in mining regions scattered all over the world, involving diverse economic conditions, is the one fitted to give to his juniors, and even to his contemporaries, the vital fruitifying information upon which technical progress depends. 'Modern Copper Smelting', by the late Edward Peters was a pioneer in this departure. Spurr's 'Geology Applied to Mining' was another example of field experience becoming joined to literary expression. But the economics of mining, the art of making money by exploiting deposits of ore, remained on the academic shelf until first Mr. Finlay and then Mr. Hoover used the spare hours of a busy professional career to set down on paper the findings of men in whom a technical training was joined to the examination, appraisal, and management of large mines operating under conditions sufficiently diverse to prevent the production of unfounded generalizations. The members of the American mining profession ought to be able to do much more in this direction. For a long time they were inarticulate; twenty years ago the standard books on mining and metallurgy were mostly the product of English writers, for example, Le Neve Foster on 'Stone and Ore Mining', Henry Louis on 'Stamp Milling', Rose on 'Gold', Roberts-Austen's 'Introduction to Metallurgy', Collins on 'Silver and Lead', Brough's 'Surveying'. Since then the technology of mining has been greatly enriched by American writers, particularly in the field of economic geology, in which Lindgren's 'Mineral Deposits' leads a long list of valuable books. The point we wish to make is that the American practitioner, not the savant, the professor, or the professional writer, has become articulate and thereby produced treatises more timely and more useful than any published previously.

DISCUSSION

Washington B. Vanderlip

The Editor:

Sir—Mr. Vanderlip, to whom you jocosely refer in your editorial note on page 859, has recently attracted world-wide attention, even as did the star *Novae Aquilae*, which burst into blazing glory some months ago. This sudden prominence is due to his obtaining a concession for Kamchatka and north-eastern Siberia, an area of 400,000 square miles.

As the public knows so little about him, and as you have mentioned him in your columns, it seems worth while to give a little authentic information. In the first place, his name is Washington B. (not D.) Vanderlip. Those who wish to know more of him should read his book, 'In Search of a Siberian Klondike', published by the Century Company in 1903. The frontispiece gives a picture of him that I took in 1900 at Indian Point, on Bering Sea. At that time we were fellow-passengers on the steamer 'Progress', which, under my charge, made a voyage from Vladivostok to East Cape, thence to Gejiga, at the head of the Okhotsk Sea and back to Vladivostok. We left Vladivostok in May and returned in October; since then I have met Mr. Vanderlip in New York, where he had an office for a time, being engaged in mining ventures; I have also met him in San Francisco and Tonopah. From these meetings I learned that he was busy looking for mines and devising inventions of many varieties; one improvement on a concentrator, I understand, proved profitable to him.

Mr. Vanderlip is an active man, perhaps a little below average height; he is of excellent physique; a fast runner, a good horseman, a good shot; he is bold, enterprising, and inured to hardship. He has that excellent power of making capitalists see things as he sees them; this was shown by his being able to interest London capitalists in financing the Gejiga expedition and has been more strikingly shown in his dealings with Lenin. He has a considerable knowledge of mining and is specially well-informed about north-eastern Siberia and Kamchatka.

Not much is known about the mineral resources of the concession. Gold is found in Kamchatka, and along the shores of Bering Sea; but whether there are valuable deposits has not been revealed. Excellent steam-coal exists within a few yards of the sea at Ugolnoi Bay. The most tangible and immediately available wealth is the fisheries. Salmon run up every river in incredible numbers.

Just what sort of a title Lenin can give to a concession in a region where his authority is not recognized is a puzzle; but if the capitalists who are back of Mr. Vander-

lip will continue to support him they have a fighting chance of making a profit.

The concession, if finally found valid, should naturally come under the consortium that has been entered into recently by Great Britain, Japan, the United States, and other powers.

W. H. SHOCKLEY.

The Broad Lode Hypothesis

The Editor:

Sir—The reading of the excellent editorial on this subject in your issue of January 8 impelled me to re-read the comment, presumably written by the editor, Mr. J. E. Spurr, in the 'Engineering and Mining Journal' of November 18, in which he takes exception in no undecided way to the definition of a lode or vein as advocated by the geologists testifying for the Utah Consolidated company in the recent litigation with the Utah Apex company at Bingham, namely: "mineralized rock or rocks which contain such indications of valuable minerals as to justify development with the expectation of finding ore. As soon as quartzite over a considerable distance becomes mineralized it becomes a lode. Just as soon as either of the rocks can produce and do produce ore, or contain indications which lead the experienced miner or prospector of judgment to develop it with the expectation of finding ore, then it becomes a lode." In his criticism Mr. Spurr uses his editorial prerogative—he has almost appropriated poetic license—to exaggerate in order to emphasize his exceptions. You agree that the definition is "so inclusive as to be unreasonable" and that it would be ridiculous were it not for the seriousness of the litigation that centred about it. An effort to construct an unassailable definition of anything is hazardous; in this instance it is particularly so because of the conflict of ideas between miners, geologists, and the courts, each of which contemplates a lode from a somewhat different point of view. However, the attempt is interesting even if futile, and I shall suggest sundry modifications whereby the definition quoted can be altered so as to avoid some of the criticism launched against it, and at the same time reconcile diverging views of the judge, the scientist, and the miner himself. The courts, following the intent of the mining statute, regarded 'ledge', 'lode', and 'vein' as being synonymous and interchangeable terms. The practical miner, however, drew an arbitrary distinction to the effect that a narrow vein was a 'vein', while a wide vein was a 'lode'; fre-

St. Paul has demonstrated to its entire satisfaction, we understand, the technical efficiency of electric locomotives when operating on the mountain divisions of its transcontinental line. From the standpoint of national economics there is nothing more inconsistent than to travel up a mountain valley behind a straining locomotive that is burning tons of precious coal or oil, while at the same time one can look down at a rushing mountain stream that, day and night, is wasting the energy that might easily be employed to pull the train. A dam, a water-wheel, an electric generator, and a system of copper wires are all that is needed to utilize the water and conserve our fuel. For years the Government has talked, and considered, and vacillated, but at last there is reason to believe that a method has been provided whereby the companies engaged in the power business can exploit our hydro-electric resources with some assurance of reasonable and sympathetic governmental protection. The Colorado is among the largest, but it is only one of many streams that may be utilized in a similar way.

'The Cost of Mining'

Elsewhere in this issue we publish a review of the new edition of Mr. James R. Finlay's book on 'The Cost of Mining'. This is one of the notable contributions to the technology of mining; with Mr. H. C. Hoover's 'Principles of Mining' it ranks as the most important contribution to the subject from members of the American mining profession; indeed, the fact that these two books were written by engineers of wide experience and high reputation is one of the reasons for their general acceptance as authoritative treatises. It may be ungracious to say so, but both books would have gained by more careful revision and closer editing, such, for example, as Dr. Raymond could have given to them. Unfortunately while modern books gain in timeliness and freshness by being written quickly and printed promptly, without the deliberation and delay usual in days gone-by when a disquisition on a progressive science or a growing industry was largely out-of-date by the time it saw the light, yet it is a pity that so many books nowadays are issued in such a hurry as to render careful revision and editing impracticable. Presumably most men prefer a book that lacks finish but is timely to one that is finished but belated; somewhere between the extremes, however, it is possible to obtain a satisfactory compromise. We make the criticism with the idea of being helpful, not of belittling the two books mentioned, which it seems to us were and are of such persistent value that they deserved more care in preparation and in printing than has been given to them. The third edition of 'The Cost of Mining' has been enriched by the addition of matter dealing with the broader aspects of the economics of mining, reflecting the author's maturer outlook. The Broad Lode Hypothesis

The Editor:

Sir—The reading of the excellent editorial on this subject in your issue of January 8 impelled me to re-read the comment, presumably written by the editor, Mr. J. E. Spurr, in the 'Engineering and Mining Journal' of November 18, in which he takes exception in no undecided way to the definition of a lode or vein as advocated by the geologists testifying for the Utah Consolidated company in the recent litigation with the Utah Apex company at Bingham, namely: "mineralized rock or rocks which contain such indications of valuable minerals as to justify development with the expectation of finding ore. As soon as quartzite over a considerable distance becomes mineralized it becomes a lode. Just as soon as either of the rocks can produce and do produce ore, or contain indications which lead the experienced miner or prospector of judgment to develop it with the expectation of finding ore, then it becomes a lode." In his criticism Mr. Spurr uses his editorial prerogative—he has almost appropriated poetic license—to exaggerate in order to emphasize his exceptions. You agree that the definition is "so inclusive as to be unreasonable" and that it would be ridiculous were it not for the seriousness of the litigation that centred about it. An effort to construct an unassailable definition of anything is hazardous; in this instance it is particularly so because of the conflict of ideas between miners, geologists, and the courts, each of which contemplates a lode from a somewhat different point of view. However, the attempt is interesting even if futile, and I shall suggest sundry modifications whereby the definition quoted can be altered so as to avoid some of the criticism launched against it, and at the same time reconcile diverging views of the judge, the scientist, and the miner himself. The courts, following the intent of the mining statute, regarded 'ledge', 'lode', and 'vein' as being synonymous and interchangeable terms. The 'practical miner', however, drew an arbitrary distinction to the effect that a narrow vein was a 'vein', while a wide vein was a 'lode'; fre-

quently his lode was comprised of more than one vein. This, of course, was neither precise nor scientific.

Geologists consider the genetic and structural features of a deposit in framing their definitions, but unanimity is lacking even among them. However, the term 'lode' has been accepted extensively as a more comprehensive term applying to ore deposits that cannot consistently be described as veins. As a matter of distinction the courts have frequently classified such deposits as 'broad lodes'. The courts have held that a broad lode need not have determinable walls. In the *Bunker Hill v. Empire State* suit it was decreed that in the absence of defined walls "the legal width is determined by the lines beyond which indications sufficient to encourage its further exploitation with the *hope* [italics mine] of profit, do not appear". The word "hope" should not be overlooked. This I believe you have done, in effect, in your editorial where you say "it does not become a 'lode' unless the mineralization is synonymous with ore; in other words, the mineralization must have been so intense as to result in a concentration of economic value, that is, one yielding a profit to the miner". I am sure you will agree that thousands of deposits, indisputably classed as lodes, have been mined for years at a continual financial loss, simply because of the hope that a shoot might be found that would recoup the owners for all of their losses. Sometimes the ore has been found, but quite as often the mine has been allowed to fill with water. Shall we say there was no lode where abandonment has resulted? Somewhere between the presence of mere mineralization (in which term, we allude, of course, to those minerals that, if found in sufficiently concentrated form, can be profitably marketed) and the presence of assured ore, there must be a point at which there is just enough mineral present to warrant the miner to continue his digging. Then he is 'on the lode', but not necessarily 'in ore'.

There is, however, another essential condition; it is that there be something to follow; there must be some distinctive characteristic in the constitution of the lode that indicates the direction in which mining ought to proceed. With the vein or lode, in its more restricted sense, the vein-matter is of a different composition and is distinguishable from the country-rock, and, except for pinching and faulting, may be followed continuously. If satisfactory indications of ore are found in one place, there is reasonable expectation of getting ore by following the vein. A bedded deposit often presents a different problem. In the *Richmond-Eureka* suit, to which you allude, the court declared in reference to the limestone bed under dispute: "Examining the features of the zone which separate and distinguish it from the surrounding country, we experience little difficulty in determining its character. . . . The broken, crushed, and fissured condition of the limestone gives it a specific individual character by which it may be identified and separated from all other limestone in the vicinity." Mineral was found in small fissures throughout this bed of limestone; when the miner found ore at one point he had a reasonable

hope of finding it by advancing in this distinctive and, broadly speaking, homogeneous bed. There was every evidence that the mineralization throughout the stratum was from the same source, that the ore deposits were genetically identical. The idea of sameness, of oneness, is an essential element in the definition of a lode and it is in this respect that the Utah Consolidated definition loses validity, and lays itself open to the pleasantries of editorial comment. Of course, the second sentence in the definition taken by itself cannot stand because "mineralized" requires further qualification; the degree of mineralization is the vital part. I suggest then the following definition: "A lode is a zone or belt of mineralized rock or rocks in place, uniformly characterized by qualities that distinguish it from surrounding masses of rock; deriving its mineralization throughout from the same source or sources; and sufficiently mineralized to warrant mining operations with reasonable expectation of finding ore."

This definition I submit with the hope that it may elicit interesting criticism; also with every expectation of having it torn to pieces by the readers of the 'Press' should you see fit to publish it.

A. G. OLOGIST.

San Francisco, January 8.

Mr. Hoover and Single-Jacking

The Editor:

Sir—On reading Mr. West's letter in your issue of December 18 I thought it might be interesting to him, and possibly others, to know that we were single-jacking in Western Australia before the advent of Mr. Hoover. I single-jacked while working for wages at Bullin Bullen, 16 miles from Coolgardie, in the year 1895 for E. R. Clifford on some properties he had bonded there from a Mr. Hurly. I single-jacked when working on wages for the Lady Shenton company at Menzies on their Florence property in the year 1896. C. H. Beaumont was superintendent and a Mr. Frye was foreman. I also single-jacked on the Florence O. Driscoll estate at Menzies in the same year. A Mr. James was superintendent and Alf. Parker was foreman. Also single-jacked at Niagara and other places in W. A. nearly 10 years previous to this. I single-jacked in the Barrier Broken Hill country about 2½ miles from the Proprietary mine out near Round Hill at a mine called the Potosi owned by Pell and McCabe of Broken Hill. A noted character named Billy O'Rourke (dubbed the Prince of Brefney) was foreman. This was in 1887 and 1888. I also single-jacked in many places through Queensland and N. S. W. before going to W. A.

While I am not in a position to know whether the Cornishman first introduced single-hand methods into mining or not, one thing I do know and that is that the Cornishman knew what a single-jack was long before the time of Mr. Hoover's first arrival in Western Australia.

MICHAEL MERRICK.

Wickenburg, Arizona, December 20, 1920.

The Greenawalt Sintering Process

By William E. Greenawalt

INTRODUCTION. The Greenawalt sintering process, the invention of John E. Greenawalt, is an intermittent operation. The basic idea of the apparatus and process is briefly and best described in the words of the original patents, as follows: "In a furnace for treating ore or other material, the combination of a porous bed or hearth, and means for passing air or gas downwardly through material and the hearth upon which it rests." And for the process: "The process of treating ores or other material upon a porous bed, subjecting the material to heat, and passing air or other gases down through the layer and the porous bed."*

The Greenawalt process, as practically developed, is intermittent in operation. A charge of the material to be sintered is placed in a pan-shaped furnace and subjected to a down-draft blast of air; the upper surface of the charge is ignited and the sintering action proceeds through the charge from the top downward. After sintering, the charge is dumped from the pan and the operation repeated.

The apparatus for carrying out this simple operation has been developed to a high state of efficiency. It is simple in operation and rugged in construction. The capacity in present operating plants ranges from 20 to 1000 tons of sinter per day. Fig. 2 shows the general arrangement of a Greenawalt sintering plant of medium size.

A complete Greenawalt sintering installation consists essentially of the furnace in which the charge is sintered; an exhaustor which creates a blast of air downward through the charge; a mixer; a charge-car; and an igniter. The mixer, the charge-car, and the igniter, may serve from one to ten or more sintering-pans.

MIXING THE CHARGE. This is an important preliminary step to sintering. A properly mixed and proportioned charge sinters readily and the resulting sinter is usually in large chunks. A poorly mixed, or poorly proportioned, charge is likely to give inferior results, in which a considerable portion of the charge has to be returned for re-sintering, whereas, in a properly mixed charge the entire mass may frequently be sintered into one large cake. The charge to be sintered should have about 10% moisture. The mixing may be done in a rotary drum like a concrete-mixer, in a rotary cylinder, or in a pug-mill. With thorough mixing, the charge becomes uniform in moisture and the combustible content is evenly distributed through the charge.

The combustible content of the charge is important. It is practically impossible to get a good sinter from a concentrated sulphide material, or from iron-ore fine,

containing an excessive amount of coke. The sulphur content in sintering lead or copper ores may vary from 5% to 15% sulphur. In sintering iron-ore flue-dust or magnetic concentrate the coke content may vary from 3% to 10% carbon. A good sinter may be made on some charges with as little as 2% carbon. Ordinarily, from 4% to 6% carbon, in the sintering of iron-ore flue-dust, will give the best results. In the sintering of copper-ore fine or flue-dust, from 5% to 10% sulphur will give uniformly good results. In sintering iron-ore fine, low in sulphur, the sulphur can be removed almost entirely. On the other hand, when it is desired to retain a high percentage of sulphur in the sinter, as in sintering copper-ore fine for the blast-furnace, this may be done by stopping the operation after the material has been sintered and before the sulphur is all removed. In cases where the material to be sintered contains too much combustible, such as coke or sulphur, the best method to adjust it is to dilute it with other fine material desired in the blast-furnace charge, such as any fine having a low combustible content. In sintering copper-sulphide concentrate the sulphur content can usually be adjusted to the desired amount by mixing flue-dust or fine crude ore with the sinter charge. In cases where such mixtures cannot well be made, as in galena concentrate, the material may be pre-roasted to bring the sulphur down to about 12% or 15%. Pre-roasted material sinters readily. The moisture in the charge, to get the best results, may vary somewhat with different material, but 10% moisture will be found a fair average. The best amount of moisture for any particular material is best determined by experiment. Usually the moisture content should be such that when a handful of the mixed material is compressed, it will retain its shape without being soggy.

In small installations, a small concrete-mixer or a small pug-mill will ordinarily be used. Hand-mixing may be done, but this is not recommended, even in the smallest plants, except for experimental purposes or as a temporary expedient.

THE SINTERING-PAN. Fig. 2 shows a typical medium-sized Greenawalt sintering-pan. It consists, essentially, of a pan-shaped sintering-furnace, mounted on hollow trunnions, and divided into an upper and a lower portion by the grates. The upper portion receives the charge for sintering, and the lower portion communicates, through the hollow trunnions, with the exhaustor, which creates a suction in the lower portion, or chamber, and causes a flow of air downward through the charge and through the hollow trunnions and exhaustor into the stack. The grates are secured to the pan and interlocked. They are easily inserted and easily removed.

*U. S. patents, No. 839,064 and 839,065, December 18, 1906.

FIG. 2. GENERAL ARRANGEMENT OF SINTERING-PLANT

tant purposes: it prevents the fine material of the charge from passing through the grate; it serves to distribute uniformly the air passing through the charge; and it prevents the charge from being sintered to the grates. If the charge were placed directly on the grates and the sintering completed, the charge would be sintered to the grates and the removal of the sinter would be difficult and expensive; besides the grates would be quickly destroyed. This porous bed acts as a buffer between the grates and the charge, so that when the pans are inverted the entire charge drops out and leaves the grate clean. The porous bed may be any comparatively non-sinterable material, such as fine sinter, crushed limestone, or crushed silicious or oxidized ore.

THE IGNITER. The ignition is one of the most important steps in sintering. Unless the ignition is uniform, the sintering will be uneven and some of the charge will remain unsintered. If the ignition is uniform the sinter will always be good on a suitable charge, and little fine will have to be returned. Manifestly, the quick and uniform ignition of the entire surface of the charge presented something of a problem, especially in connection with the 10 by 24-ft. pans. This problem was thoroughly solved by the ignition-hood, or igniter, which temporarily covers the charge while the ignition-fuel is projected over the entire surface of the charge. The air for the combustion is sucked through the numerous perforations in the hood.

The ignition-fuel may be oil or gas. Both are being used successfully. Crude oil is satisfactory. Distillate, or kerosene, is a good ignition-fuel if cheaply obtainable. Gas is usually cheaper than oil. Either natural gas, blast-furnace gas, or producer-gas may be used and are giving excellent results. The combustion should be complete. A sooty flame is not as good as a flame which does not show any unconsumed carbon. The oil or gas is so finely atomized and so intimately mixed with the intruding air through the perforations in the hood that there is little or no difficulty in getting a clear flame. When the combustion is complete the temperature in the igniter is intense. The ignition can usually be made in a minute. The

igniter, itself, does not become very hot; this is due to the cool inrushing air and to the momentary time required for ignition.

In the operation of a commercial plant the igniter is mounted on wheels and runs on the same tracks as the charge-car. The hood, or igniter, is normally about half an inch above the upper rim of the pan, so that it can be freely moved over all the pans. When ignition is to be made the hood is temporarily lowered, and makes a close connection with the pan, so as to give a uniform ignition over the entire surface of the charge, and especially around the edges. If it were not for this, the inrushing air around the perimeter of the pan would divert the flame, and result in incomplete ignition. When the ignition is made, the hood is raised, and the igniter is ready for another pan.

After the ignition has been made the sintering of the charge proceeds without the igniter. The igniter is usually motor-driven, the same as the charge-car. For the smaller pans the igniter may simply be pushed from one pan to the other. If oil is used for ignition, it will usually take from 0.75 to 1.0 gallon per ton of sinter. In a small plant, in Mexico, sintering copper concentrate and flue-dust, the oil consumption was materially reduced by sprinkling a little waste coke or charcoal dust over the top of the charge. It was found, in this connection, that if fine coke or charcoal were mixed with the sinter charge of copper concentrate and flue-dust, that much of the carbon would remain unconsumed and fixed in the sinter so as to make it available in the blast-furnace.

SINTERING THE CHARGE. The sintering of a charge may be briefly described as follows: The mixed material, as also the porous bed, is delivered to the charge-car; the car is then run over the pan, and in passing over it, the porous bedding is uniformly spread over the grates by the distributor at the front of the car, and the charge immediately placed upon the bedding and levelled off with the top rim of the pan. This usually takes less than a minute, even for the 10 by 24-ft. pans. The exhaustor is then started, or switched on to the pan. This creates a strong downward draft of air through the charge. The igniter is then run over the pan and the ignition-fuel, under a high pressure, is atomized over the charge and ignited. The flame and hot products of combustion are sucked down through the charge and completely ignite the surface, usually in less than a minute. The igniter may then be removed and used for another charge. The sintering proceeds until the entire charge is sintered. The time of sintering may vary from 15 to 60 minutes, depending on the nature of the material and the results desired. The suction may vary from 10 to 35 in. of water. It is usually more at the beginning than at the end of the operation, for the reason that at the beginning the mass is not as permeable. With a high suction, there is not so much danger of short circuits of the air through the charge; when a short circuit occurs, the temperature at that point becomes so intense as to cause fusion, which automatically has a tendency to close the larger air-passages through the partly sintered charge, and make

the sintering more intense at other portions. When the sintering is complete, the exhaust is shut-off, the pan mechanically rotated, and the sinter dumped. The pan is then rotated back to its normal position, and the cycle repeated. In some of the large plants the cycle is completed in about 20 minutes.

The power required for sintering depends somewhat on the nature of the material to be sintered. Ordinarily it will be from 5 to 6.5 kw-hr. per ton of sinter. The repairs are small and consist principally of the replacement of grates.

FLEXIBILITY OF THE PLANTS. The plants are exceedingly flexible, both in installation and operation. It will be noted that the charge-car and the igniter are used only a few minutes for each charge. Similarly, in the first unit, the mixing, conveying, and elevating machinery, will usually be far in excess of the requirements, or can be cheaply made so. The capacity of a one-pan plant can therefore be doubled at any time and at small expense, by simply adding another pan. It may be trebled by adding two pans, etc.

The plants may be operated as desired; each pan may be operated independently of the others, and one, or all, of the pans may be operated for one or three shifts, since each cycle of sintering in each pan is complete in itself. This makes it possible to start with a small installation, and later, if desired, the capacity can be increased as needed. Or, in a plant normally operating a number of pans for 24 hours, any of the pans can be cut out at any time and the working force reduced to one shift without materially affecting the operation, so far as the apparatus is concerned.

PRELIMINARY SINTERING-TESTS AND APPARATUS. The sintering results on any material can readily be determined by the Greenawalt process with a small laboratory equipment, as shown in Fig. 1, made by the Colorado Iron Works Co. of Denver. Any good mechanic can set it up at the works ready to operate, in a few hours. This equipment represents a unit of all the working pans. The suction is obtained by connecting the Schutte-Koerting ejector to a steam-boiler. It has been found by years of experimentation and testing with such an equipment as this, that the results obtained in this small pan are absolutely reliable, and can be duplicated in the commercial installations. There never has been a single disappointment when commercial plants were installed on the basis of the results obtained with this miniature Greenawalt sintering plant, which, it must be remembered, represents a full-sized section of all the pans. A water-gauge records the suction, and the suction may be varied as desired for different charges. This small pan holds about one cubic foot of the material to be sintered. It offers a cheap and convenient apparatus for trying out the sintering qualities of different mixtures and with various suctions.

OPERATING GREENAWALT PLANTS. There are a large number of Greenawalt plants in operation in different parts of the world, sintering various materials, and varying in capacity from 20 tons to 1000 tons per day. There

have been two 1000-ton plants in operation for some time; one sintering magnetic concentrate, and the other sintering iron-ore flue-dust. Both are now being enlarged to a capacity of 2000 tons per day. The 10 by 24-ft. pans are used in these plants. The sinter is dumped directly into a train of railroad cars and shifted to the blast-furnaces. Smaller plants are in operation sintering lead ore, copper concentrate, iron ore, and copper fine and flue-dust.

SINTERING V. DRYING OF TABLE AND FLOTATION CONCENTRATE. Several interesting problems arise in reference to sintering by the present method. One is the possibility of sintering concentrate for shipping instead of drying. Sintering requires about 10% moisture. Drying of the concentrate, if sintering is contemplated, would therefore be unnecessary and could be eliminated. Concentrates contain their own fuel for sintering, as opposed to extraneous fuel which has to be purchased for drying. The sinter would be ready for smelting, and the shipping weight would be reduced to from 15% to 20% from the ordinary dry-shipping weight. This reduction in weight is due to the replacement of the sulphur with the lighter oxygen, to the elimination of the water of hydration, to the elimination of other volatile elements, and to the evaporation of the uncombined moisture, which in ordinary drying is never complete. A reduction of from 15% to 20% in the shipping and smelting weight will ordinarily much more than pay for the sintering. If the sulphur content in the concentrate is too high for sintering, the charge can almost always be diluted with fine shipping ore low in sulphur, and this would tend to give a greater porosity to the sinter charge, especially in the sintering of flotation concentrate. The following advantages would, therefore, be gained by sintering instead of drying: First, drying would be entirely avoided, since the moisture is necessary in the mixed sinter-charge. Second, the concentrates furnish their own fuel for sintering (except the ignition-fuel) as opposed to the fuel which has to be purchased for drying. Third, reduction in weight both for shipping and smelting of from 15% to 20%. Fourth, the saving in sacking, where the fine concentrates are sacked to prevent excessive loss. A sinter-pan for this work could be cheaply installed. The sinter would, of course, be more desirable for the smelter than the raw concentrate, but while this might be of interest to the smelter, it would be of no interest to the shipper, unless some small allowance should be made for the better character of the material.

SINTERING AND BLAST-FURNACE SMELTING V. ROASTING AND REVERBERATORY SMELTING. The sintering of fine ore and concentrate brings up the very interesting problem, in copper smelting, as to the relative merits of blast and reverberatory smelting. The pendulum, which swung from the blast-furnace to the reverberatory, may swing back again. The roasting of sulphides preparatory to smelting, may be somewhat cheaper than sintering, but the difference is not serious. The dust, in roasting of fine sulphide, is considerably more of a problem than in sintering the same material, for sintering produces only a small amount of dust as compared with ordinary roast-

ing. The sintering of sulphide, such as flotation concentrate, presents a difficult but not insurmountable problem. It also presents a problem in ordinary roasting. In reduction-works, smelting both mine ore and concentrate, the conditions are different. The elimination of the fine material from the blast-furnace greatly increases its capacity, and the sintering can usually be made a method of satisfactory fluxing. In one installation, under the writer's general direction, the capacity of the blast-furnace was increased from 85 tons per day to 250 tons per day on a test-run of the Greenawalt equipment. This increased capacity was primarily due: First, to the sintering of sulphide concentrate, high in iron as well as in gold and copper; the product was used as a flux, which was lacking in previous operations. Second, to the elimination of a large portion of the fine material from the blast-furnace charge by mixing with the concentrate to form the sinter. Third, to some changes in the design of the furnace. In the previous operations 25% limestone was added as a flux; this was in whole or in part replaced by the high-iron sinter in the test-runs. A higher-grade matte was also obtained. It was highly profitable to replace the barren limestone flux, with a high-iron sinter, having from \$20 to \$25 in gold and copper per ton. The concentrate was from mine-ore too low in grade to smelt direct. The dilution of, say, a \$10 smelting ore, with 25% barren limestone as a flux, would make a furnace-charge worth about \$7.50 per ton; the enriching of the \$10 ore, by fluxing with a high-iron sinter having, say, \$20 in gold and copper, would give a furnace-charge worth \$15 per ton, as compared with \$7.50. The cost of smelting a ton of \$15 mixed charge would not be any more than for smelting a ton of the \$7.50 mixture, either for fuel or labor. It would probably be less. In the particular instance cited, it was considerably less.

There are many conditions, however, to be considered in blast and reverberatory smelting. The fuel available will probably be the determining factor in most cases where both methods are applicable.

A RECENT ISSUE of the 'Journal du Four Electrique' contains a description of the process introduced by Gustav Laval and worked by the Norsk Elektrisk Metal Industri, at Sandlokken, Norway, for the electro-thermic distillation of zinc by direct treatment of the ore. The plant comprises a series of electric furnaces having a daily capacity of from 3 to 5 tons of zinc each. This method is said to result in a considerable saving of labor and fuel. At present 15,000 tons of ore per annum is treated at the works, and the company is completing a new hydro-electric plant on the west coast of Norway, with a capacity of 30,000 hp., for applying the Laval process on a larger scale.

FROM July 1 to September 30, 1920, inclusive, 2045 flasks of quicksilver, of 75 lb. net, was produced in the United States. If the present rapid decline continues, as now appears probable, the total for the year will be less than 12,000 flasks, 9000 flasks less than for 1919.

Engineering Foundation: Its Work and Needs

By ALFRED D. FLINN, Secretary

Engineers and scientists have created modern civilization. They have founded it upon facts, won by research from the inexhaustible storehouse of Truth. Simultaneously they have put into the hands of the enemies of civilization the weapons of destruction. That American engineers in many ways aided in averting the recently threatened catastrophe, is generally acknowledged; but one of their instrumentalities is known to few even among engineers. To this instrumentality the world war was no more than a great event in its childhood; it looks forward to unmeasured years of service in peace and progress. If, however, war should again become inevitable, again will this instrumentality be one of the readiest factors in preparedness.

In 1914, Ambrose Swasey, of Cleveland, Ohio, a past-president of the American Society of Mechanical Engineers, gave to the United Engineering Society the sum of \$200,000 as the nucleus of a trust fund, the income from which should be used "for the furtherance of research in science and engineering, or for the advancement in any other manner of the profession of engineering and the good of mankind". The United Engineering Society, as the incorporated board of trustees holding joint properties for the American societies of civil, mining, mechanical, and electrical engineers, organized the Engineering Foundation Board to administer the income from the trust-fund. The Foundation was allotted offices in the Engineering Societies building, New York. In September 1918, Mr. Swasey gave an additional \$100,000.

In April 1916, the National Academy of Sciences offered to President Wilson its services in organizing the scientific resources of the country in preparation for the evidently unavoidable participation in war. In response to a request from the President, the Academy, with the co-operation of the national scientific and engineering societies, organized the National Research Council. No fund and no home having been provided, Engineering Foundation offered its offices, its financial resources, and the service of its secretary for one year from September 1916. Thus, as its first work, the Foundation succeeded the Research Council until greater provision from private and governmental sources could be made. Through the Foundation and the national societies the engineers co-operated with the Council during the War and in the period of reconstruction; they have a permanent place in its peace organization and projects. National Research Council now has an endowment of a few millions and a fund for the erection of a suitable building at Washington.

The Engineering Foundation is a response to the need for research, other than that of the Government and of large corporations, beyond the means of individual engi-

neers, small companies, and separate societies. The Foundation has an endowment of \$300,000, an organization based on the national engineering societies, and means for publicity. It can receive and administer funds; support researches by individuals or organizations; establish and operate laboratories; aid in applying the results of research; stimulate interest among engineers, and enlist support for these purposes.

For the engineering societies, Engineering Foundation is their joint agency for research, and a liaison with scientists through the National Research Council. With National Research Council, the Foundation co-operates in stimulating and co-ordinating research by governmental, educational, industrial, and private agencies.

The Council has a Division of Engineering, the purpose of which is: "To promote research and the application of the sciences to engineering." Engineering Foundation may use its funds "in any manner, for the furtherance of research in science and engineering". Therefore, Engineering Foundation may undertake any kind of work that the Division may undertake, and others besides. Confusion is avoided through the intimate relation between the Foundation and the Council and frequent communication between the offices of the Foundation and the Division. Even in their common field there is work enough for both; and by agreement upon program from time to time, interferences will be escaped. The peculiar value of the Division arises from its being an integral part of the National Research Council, the national federation of scientists and engineers for promotion of research, and therefore being in a position to place before scientists the engineering problems that require scientific research, and to inform engineers of the activities of scientists that may affect engineering. Engineering Foundation can contribute to the support of the Division, can share in its deliberations through interlocking membership, can benefit from its work, and can have its advice as to researches that may profitably be supported by the Foundation. Independently, the Foundation may establish and maintain laboratories, support or conduct researches, and contribute results to the engineering societies. The Foundation and the Division each is essential to the engineering profession for purposes of research, but the activities of the two must always harmonize.

With the scientific bureaus of the Government, the Foundation can exchange information; make more available to engineers results of researches by the bureaus; suggest to the bureaus how to make their researches more helpful. To the Engineering Societies Library, the Foundation can extend aid in making this library the repository of all information about research relative to engineering.

What needs can the Engineering Foundation supply better than any other organization? Direction and support of research relative to engineering, of such nature as not to be undertaken by an industrial corporation, the Government, or a university; collection and publication of information about research of particular interest to engineers, utilizing engineering journals.

Should Engineering Foundation establish an Engineering Research Institute and Laboratory? Some thoughtful men believe that it should, to supplement the university training of promising researchers; to provide place and means for research by engineers and inventors, and for limited co-operative research for industries. The laboratory might be made partly self-sustaining. For some kinds of work or training, charges might be made, particularly for those not of general interest, and for those from which a profit will be realized. An establishment under Engineering Foundation would have an independence and celerity of action not feasible in a governmental laboratory and would be able to conduct researches on a scale and in an atmosphere of practical requirements not possible in a university. In the course of years, there might be more than one laboratory, each situated where it would have the best conditions and be most useful.

By conserving for a few years a large part of its meagre income Engineering Foundation was able, in May 1919, to appropriate \$30,000 for the support of an extensive research in the fatigue phenomena of metals. This expenditure will be spread through two years. The tests are being made at the Engineering Experiment Station of the University of Illinois under the general auspices of National Research Council. The University contributes certain services, equipment, and facilities, and provides the working-space, estimated as equivalent to \$12,000. Some manufacturers are furnishing specimens. Recently the General Electric Company, one of the largest industrial corporations in our country, asked to have the program of tests broadened, at its expense, to an amount equal to that provided by the Foundation. The purpose of all these investigations is to obtain further knowledge about the behavior of parts of machines and structures subjected to many repetitions and variations of stress. These tests are in active progress under the direction of H. F. Moore, assisted by J. B. Kommers, of the University of Wisconsin. The expenditure will probably total \$75,000.

From fifty or more suggestions received from many sources, the Foundation Board selected from time to time for investigation a few that demanded only small expenditures. A study of the wear of gears begun in 1916 was interrupted by the War, but was resumed in the summer of 1920. It is being conducted at Stanford University, by Guido H. Marx and Lawrence E. Cutter. To aid in solving the problem of protecting ships from attacks by submarines, Engineering Foundation, in November 1917, joined with the New York committee on submarine defence in making, under the direction of H. P. Quick, experiments on concealment by means of spray from special nozzles disposed at suitable points on the

ship. The U. S. Navy lent a barge and other equipment. A number of tests made in New York harbor led to the conclusion that the method was not practicable. Foundation made a small appropriation for a special study, at Columbia University, of some features of the secret directive control of wireless communication.

Many experiments have been made upon weirs as a means for measuring flowing water and other liquids. Several elements of the problem remain unsolved, and others have not been satisfactorily solved. In December 1918, an appropriation not to exceed \$2500 was made for an investigation to be conducted under the direction of Clemens Herschel, hydraulic engineer, in collaboration with the hydraulic laboratory of the Massachusetts Institute of Technology. This investigation resulted in an improved form of weir for gaging the flow of liquids in open channels. Mr. Herschel presented his report in the form of a paper at the spring meeting of the American Society of Mechanical Engineers, at St. Louis, in May 1920.

In December 1918, Julius Alsberg, consulting hydraulic engineer, suggested the establishment of a testing-station for large water-wheels and other hydraulic equipment. Silas H. Woodard, H. Hobart Porter, and Calvert Townley were appointed a committee to inquire into this subject. This committee reported in May 1919, that such a testing-station was not practicable, that it is not advisable to establish a testing-flume for small models because existing flumes meet all requirements, but that testing of water-wheels now in place would be useful and practicable.

In February 1919, the Foundation authorized E. E. Southard, director of the Massachusetts State Psychiatric Institute, to make a preliminary investigation as to the part played by mental abnormalities in industry. Upon the presentation of a report in May, showing satisfactory preliminary results, for which an expenditure of \$300 had been made, \$2500 was appropriated for a research in mental hygiene of industry to be made under Dr. Southard's direction during the year beginning June 1, 1919. W. F. M. Goss, J. Parke Channing, E. W. Rice, Jr., and Thomas T. Read were appointed an advisory committee. The objects of this research are to develop or discover methods for adapting psychopathic individuals to usefulness in industry and to prevent them from becoming sources of disturbance, in so far as these ends may prove attainable. Dr. Southard died suddenly on February 8, 1920, leaving much of his work unfinished.

The Foundation Board realized, however, that the research in mental hygiene of industry dealt with only one of many elements of the industrial personnel problem. Therefore, in June 1919, the Board addressed to the National Research Council a letter proposing a co-ordinated broad research in problems of industrial personnel. In response, the Council appointed a committee consisting of representatives of its divisions of Anthropology and Psychology, Educational Relations, Engineering, Research Extension, and Medicinal Sciences, the secretary of Engineering Foundation, and the chairman of the National Research Council, to consider means of furthering the study of the problems of industrial employment.

Storage-Bin With Louvred Hoppers

By NEWTON L. HALL

Difficulty is frequently experienced in preventing 'hang-ups' in storage-bins. Delays are caused which are expensive not only because of the additional work required to get the material again into motion, but because of the time lost in subsequent operations due to the interruption of service.

Most bins have closed or continuous sides and this rule generally applies to the gates, the feeders, and the hoppers. A tight bin is sometimes necessary, but not often. Barring tightly packed material with a long rod from above the bin is a tiresome and expensive operation. Hammering the sides of the hoppers with heavy sledges is inadvisable, and yet it is a common practice when bins for custom ore must be thoroughly cleaned before the next charge is received.

The discharge opening of a bin can be made to retain the material, no matter how finely it is ground, by placing openings or 'louvres' over the gate-opening, that is, 'flash-boards' placed at an angle but in vertical line with space between them. The spacing of the boards is arranged according to the angle of repose of the particular material. This idea can be applied to the sides and hoppers of storage-bins, which, for the want of a more appropriate name, can be termed a louvred bin.

In its design, a louvred bin of wooden construction is framed in much the same manner as a plain bin. In the accompanying sketch the wooden bin has a double sloping bottom with central-discharge openings. The first two boards over the diagonal beams of the framework are laid as they would be in a plain bin. Above this first course and on the diagonal beams of the frame, wedge-shaped cleats of the width of the beams are laid with their points upward, and over these cleats the next course of two boards is placed so that there is a vertical opening between the top of the first and the bottom of the second course. Succeeding courses above are placed in the same manner with a louvre-opening between. These courses should be 24 or 30 in. wide with a 4-in. louvre between each course.

At the corners of the bin, where the sloping bottom meets the vertical sides, another louvre-opening should be provided by extending the bottom out and beyond the vertical siding so as to leave a 4-in. vertical opening at the junction of the two sides.

The load within a plain bin tends to pack as it descends toward the discharge-gate opening. Usually no means are provided to relieve this tendency to pack. The sides

of the bin are so formed that the weight and convergence of the load accumulates its pressures to an extent that causes that part of the load next to the bin sides to stick, and if the ore is not dry, the centre of the load moves and causes a 'piping' of the outer part.

In a louvred bin the load descends as in a plain bin, but at each louvre-opening the friction against the side is decreased and the accumulation of pressure relieved. When the load does stick it can be prodded through the louvre-opening from the outside. The louvred bin serves two distinct purposes: it can be designed to maintain the mobility of any granular load, and it exposes the load

so that it can be barred or prodded from the outside at the most advantageous point.

The principle of the louvre-opening can also be utilized at the gate-opening. Bins are frequently constructed with the discharge-gates in the side of the bin as if the first object of the gate was to close the opening perfectly tight, and yet a louvred gate would give better service. Placing the gate a short distance away from the bin and leaving a space between the gate and the bin open at the top not only removes the gate from much of the direct pressure of the load, but allows the load to assume an angle of repose before reaching the gate.

Milling plants throughout the country too frequently have bins that are of needlessly tight construction; their loads are inaccessible, whereas an open construction would give better service. Bin-gates are made of complex design when all that is required is a simple gate proportioned to the size of the material. Designs incorporating the louvre are not new and their practicability has long been demonstrated. A liberated load brought to its natural repose ceases its movement and localizes its zone of action. The application of this principle is illustrated in the design described in this article.

A Defence of Minerals Separation

By Alfred A. Cook

*I wish that I could have had the opportunity of familiarizing myself with the papers read by Mr. Nye and Mr. Montague before they were read. I might then have had the privilege of presenting to you in written form such views as I thought might be germane to the discussion and helpful. I say "helpful", because I think that anything which affects the mining industry, should prompt anyone interested in any of its component parts, to do his share in the work of usefulness and co-operation. I could then have eliminated all things which were not controversial, and could have reduced a discussion of differences to fundamentals and the facts.

What did the American Mining Congress do? Instead of coming to us or even writing to us through its secretary, it filed allegations and charges, and impressed the Federal Trade Commission with the fact that the Minerals Separation Companies are German-owned and German-controlled. A year ago at St. Louis, an address was read by Mr. Nye, page after page of which charged Minerals Separation with functioning in this country as a German-owned and German-controlled concern. Now, to my mind unless the facts substantiate a charge of that kind, that is going not only far afield but is hitting, if I may say it, below the belt.

In this article the assertion was made that two gentlemen residing in England were in effect secret German agents and through their ownership or control of a majority of the shares, arrangements were made so that Minerals Separation could function in this country as a German-owned and German-controlled company. Who were these two? If any of you have some of these reprints I refer to, you can see mention of the names of Kindersley and Pusch. Who were they? Kindersley is Sir Robert Kindersley, a director of the Bank of England, Governor of the Hudson Bay Co., and throughout the war the head of the War Savings and Victory Loan movement of England, recently knighted and given by his King the honors that fall to honest and deserving patriots. And who was Pusch? A Russian who came to England years ago, a naturalized Englishman who lost two of his sons, officers in the English cavalry in the war, and when England sent a commission to Russia during the war he was either one of the members or the head of that commission.

Now, of course I know the force and effect of propaganda. I know that a rumor here and a rumor there grows and grows and forces itself throughout any industry, throughout any community, and even gets to the ears of the Government, and so, practically at the instigation of the American Mining Congress, we had visited upon us for weeks and months the Alien Property Cus-

todian, who goes through our affairs from beginning to end to determine whether this charge of German ownership and German control is correct. And the Bureau of Mines comes, and the Federal Trade Commission comes, and every conceivable Government agency. You heard this morning the reading of the articles from the Canadian press. Away back in 1917 the Canadian government examined us. You heard the charge made, that if in Canada royalties are unreasonable, the patent is forfeited; and yet after all that investigation by the Canadian government, Minerals Separation cleared itself completely. Now, there must be some reason and some element of justice in the decision. Of course, you may very properly say: "Well, this charge of being German-owned and controlled is an old thing," and so forth and so on. I am speaking of it to you, because I never believe in fighting a fight through newspapers, or periodicals, or other journals, when there are properly constituted tribunals before which to wage the fight. So far as the two gentlemen whose names were mentioned are concerned, I did call the attention of the Mining Congress to the great injustice that it had done them, and to its credit be it said that an apology was forthcoming.

Let me take up another matter. Recently there appeared in the 'Engineering and Mining Journal' an article headed: 'Western Hearings of Minerals Separation Companies by Federal Trade Commission', and there were quotations in that article, or attempted quotations, as there were quotations this morning. I have not had the opportunity to read the quotations in the article read this morning, so I do not know whether everything was there or whether the cross-examination affecting the various matters was there, or whether there were eliminations and the usual stars to denote eliminations. Just let me however call your attention to this particular quotation appearing in the article just mentioned. This statement is made: "One licensee who testified that his relations with Minerals Separation had been pleasant said: The royalty is too high * * * We regard it as entirely too high * * * It becomes a very burdensome charge." Now, those words were used, but they were used in connection with other words, and my only thought on the subject, as long as we are going to have a fight, if it must be and I hope it need not be, let us be fair with each other and play the game. This is what was testified to by the witness: "I do not say I regard it as too high under those conditions. I say, under present conditions we regard it as entirely too high. When I am not making any money at all, it becomes a very burdensome charge." Whether that is helpful to the Mining Congress or not, we were entitled at any rate to have quoted what was said.

You heard this morning in, I think, Mr. Nye's address,

*Extracts (by the Editor) from a speech delivered before the American Mining Congress on November 17, 1920.

something about Mr. Nutter using the language "sinning against some one" or other, and yet, Mr. Nutter was not responsible for that. Mr. Nye might have told you that Mr. Hawkins, representing the Federal Trade Commission, when he put the question said: "What were Mr. H's sins, what was his infringement, how was he sinning?" And that Mr. Nutter then answered as quoted. Now, in the article that I refer to, in order no doubt to impress the representatives of the American Mining Congress that Mr. Nutter did not know what the infringements were, and that he simply charge infringement without any knowledge of the facts and that adjustments and settlements were made by reason of power or coercion, or call it whatever you please, Mr. Nutter was quoted as saying "I don't know". This however is what is omitted: "He admitted that he was infringing, so I did not go back of his statement to me." Now, take another instance referred to, that about the Evergreen Mining Co., where, Mr. Hollister, I believe, was asked: "If you do not fear the litigation by the Minerals Separation Company, with the price of copper as it is now, would you reopen your mill or not?" and he answered "Very probably we would." If however you examine the testimony of Mr. Hollister, you will find that he said that they had troubles at the mill with their machinery and it was on that account that it was closed. It is very short so I will read the testimony.

Q. Did you sell your concentrates prior to 1917?

A. Yes sir.

Q. What do you mean by operating on a commercial basis? Operating on a profit?

A. No, we were in such bad shape up there that our mill was closed down most of the time, and it was entirely experimental and not satisfactory as an experiment by any means.

Q. What do you mean by 'bad shape' of your mill?

A. Well, our machinery was not adapted, our grinding machinery was not adapted to the work we wanted to do.

Q. Did Hyde have anything to do with your grinding machinery?

A. I beg pardon?

Q. Did Hyde have anything to do with your grinding machinery?

A. No, he did not."

And there you will find it, if you want the reason why the mill was closed down and shut. It was not because of Minerals Separation.

Let me call your attention to one other thing. When I asked Mr. Hollister on cross-examination what oil he was using, and whether he was using less than 20 lb. of oil to the ton of ore treated, he declined to answer, he declined to answer that question, as many other of the witnesses declined to answer the same question. Now, gentlemen, either there was infringement or there was not. If this matter is to be handled in a big broad open fair and honest way, a man does not mind the question as to the amount of oil he is using. If he is not infringing, he does not care. I want to say for some, that with courage and fearlessness they mentioned what they were doing

and what they were using. Even though Mr. Hollister was told that no testimony that he would give would be used against him in any proceeding in the future, he declined to answer and yet we are told that when we have Mr. Henry D. Williams write a letter to the Evergreen Mining Co. and others to stop infringing, we are threatening them, we are coercing them, we are abusing them, and we are doing things which the law condemns. If we did all these things, here was the chance and the opportunity on the part of Mr. Hollister at least to prove beyond doubt that at any rate, so far as our letter to him was concerned, it should not have been written. Why was it written? Because the Patent Law says, as I understand it, that if you learn of infringement you ought to give notice of some kind to the infringer of your rights.

I am somewhat limited in what I can or want to say. As Mr. Montague put it this morning, pointing to the many volumes of testimony, "there is only a part of the record and more is to come". Our side has not yet been heard from, and I cannot tell you everything. I can try to tell you a few things. There is one situation however I will not be able to discuss, and that is the patent situation. I am not a patent lawyer, nor do I think that arguments pro and con between the lawyers on each side, or the submission of patent questions to the Mining Congress, can bring forth anything useful unless it be with a view to determine first what each claims. I shall not speak of patent law, if for no other reason than that the various matters are before the courts, and so far as I am concerned, they are in the hands of patent counsel, and I do not think it would be correct or proper for me professionally, to discuss a situation which, as lawyers put it, is *sub judice*.

I do want however to make one comment, subject to correction by my company or the patent lawyers, should I be wrong. I speak of it now because I notice it interested Dr. Cottrell, as it very properly should. I understood Mr. Montague to say that if any particular company is using the oil patent, 835,120, that when that patent expires in 1923, and a licensee of Minerals Separation uses no other of its patents, that, nevertheless, beyond 1923, the expiration date of the patent, Minerals Separation claims the right to continue to exact royalties from its licensees, until the crack of doom, or as he more nicely put it, as he always does: "Until the end of time." I may be wrong, and the question as to whether I am right or wrong can properly be determined and easily upon inquiry, and will be determined. That is not my understanding. In other words, if when 1923 comes, and a licensee does not use any of the Minerals Separation patents at all, I do not understand that he must pay any royalty to Minerals Separation. If, when the 1923 patent has expired, and he uses any other patent, let us say the soluble frothing agent patent, then his royalty continues. If he ceases using it, he pays no royalty. No licensee is called upon to pay any royalty unless he uses a Minerals Separation patent within the period allowed by law. Please let it be known by the

members of the Mining Congress that it is my understanding, subject to correction by Minerals Separation or its patent attorneys, that when the 1923 patent expires and a licensee uses no other patent, he pays no royalty. If he uses our 1927 patent, or any other, then, being a licensee, and using our patent, he must pay royalty. If when 1927 comes and he does not use any of our patents, why then, of course, as I understand it, and subject to correction as I have stated, we cannot exact or ask or claim any royalty from our licensee. I say that because I feel that when the patent expires and it is not protected any more, it is open, and I cannot conceive, or better, I cannot understand how the contention arose. When I say I cannot understand, it may be, and it is possible, that my understanding on this patent matter is entirely wrong. Whether I am right or whether I am wrong however the Mining Congress and the public, are entitled to know what our attitude as to that is. I have stated to you what I understand it to be, subject to correction.

You listened patiently, as I did, this morning, to the reading of a great many extracts from a license agreement; and yet, gentlemen, why the old license agreement of Minerals Separation, abandoned in December 1917, should furnish the gravamen of charges made against us, is absolutely beyond me. There is no justification for referring to our old license agreement when we have a new one which has eliminated from it a great many features which were criticized in one of the addresses of this morning. I will discuss with you why the provisions were in the old license agreement as they were, because there was some reason for it. Since December 1917, however, there has never been a time under our license agreement, when a manufacturer of a flotation machine could not sell his flotation machine to any licensee of Minerals Separation Company. All we require is that the licensee should ask our consent to its purchase. You may say: "Well, you didn't have to give your consent if you didn't want to." Our new license agreement specifically says we *must* give our consent. That eliminates from the situation the question whether any maker of a flotation machine can sell his machine to any licensee of Minerals Separation. In other words, if the John Jones Mining Company wanted to install the Ruth machine or the Grouch machine, or the K & K or the Janney machine, or the Callow cell—the John Jones Mining Company need only ask us and we are obligated to give our consent. We merely state that we do not hold ourselves responsible for anything that may happen by reason of the use of somebody else's machine. Let me show you the way that works. A little while ago there was sent by the Pneumatic Process Flotation Co.—I believe that is Mr. Callow—to the mining fraternity, a statement that the company were owners of a certain machine, and so forth, and controlled certain patents, and that anybody using that machine and so forth, infringed the patent, and they were going to hold such a one liable for such damages as were allowable by law for infringement. We received a letter from

a licensee in Boston, sending us a copy of this particular statement telling us that it was not going to pay any more royalty, and that we were called upon, under our license agreement, to defend against any suit that the Pneumatic Process Flotation Co. might bring. Now that is why, when our consent is given, we say we will not be responsible for anything that may happen by reason of the use of somebody else's machine.

I am not trying to sell or advertise the standard machine of the Minerals Separation. Whether you have it or not is a matter of indifference to me. I do want to state this, that if a mining company had been using a Minerals Separation standard machine, we would then have defended our licensee against a suit brought against our licensee by the Pneumatic Process Flotation Co. if the charge was made that our machine infringed upon the process or machine claimed to have been owned by the Pneumatic Process company.

Reference was made to the license agreement, I think it is Section 3, and it was stated we had demanded or claimed or insisted that the employees of all of the licensees *had* to assign and transfer to Minerals Separation whatever they invented. Now, gentlemen, that is also the old license agreement; that clause is not in the new license agreement. I will read from the license agreement. The third article reads as follows: "Licensees, shall, during the continuance of this license"—and I do not say that so far as the licensees are concerned that the licensees are not obligated to transfer their patents—that is quite correct—but I am discussing the question of their employees, and I will tell you why later, why the licensees are called upon and the employees not—"Licensees shall, during the continuance of this license, promptly communicate and explain to licensors every invention or discovery made or used by them which may be an improvement, modification or addition to any of the inventions specified in the letters patent within this license, or may be useful in carrying out any of the processes thereby perfected, or any additions thereto, or modifications thereof, whether patentable or not." It then reads that the licensees will use their good offices to induce their officers, agents, and employees, to assign or transfer to the licensors any inventions made by such inventors upon terms mutually satisfactory to said licensors and said inventors. As I said before, the officers, agents and employees of the licensees who invent or discover, are not obligated to turn over to Minerals Separation their discoveries, if made as individuals; and to prove to you that this has not borne heavily on the mining industry, I should state that there has not been one single patent of Minerals Separation ever obtained from any licensee. There were two or three patents, it was testified to before the Federal Trade Commission, which were obtained from employees of licensees.

They were purchased however by the Minerals Separation Company, and in one instance where one of the employees demanded of Minerals Separation a price in excess of that which Minerals Separation thought proper

or fair the employee sold his patent to somebody else. That is the length and breadth of this story. Now, do not misunderstand me. We were asked quite recently by an intending licensee who, incidentally, was a witness against us in the Federal Trade Commission proceedings, but who listened to the testimony and evidently had his mind disabused of some of the things that had lingered in it, for an interpretation of this clause of our license agreement. This was written to him and may be regarded as having been written to you.

"In compliance with your request we are pleased to confirm what we said to you the other day at our conference with respect to our interpretation of those portions of section three of the license issued by us which, assuming the licensee to be a corporation, you thought conflicting. The first part of section three seeks to cover patents acquired by such corporations, or of which the corporation becomes the outright or beneficial owner. The latter part of Section 3, namely, that referring to officers, agents and employees, applies to them as individuals, and what they do as individuals, as separate and distinct from what they do as officers, agents or employees of the corporation. What the officers, agents and employees invent or discover as individuals, and not as officers, agents or employees of the corporation, is their own property, unless it be that by agreement with the corporation they are obliged to turn over to the corporation that which they, as such individuals, invent or discover. All agreements, and the conduct of the parties thereunder, must be measured by good faith, and where good faith actuates the parties there ought to be little opportunity for controversy."

Now, I mention to you that we are now obliged to give our consent to the installation of any machine to work the flotation process. At the very foot of Section 3, from which I read are the following words:

"On written request, consent will be given by the licensor who, however, assumes no responsibility or obligation whatever by reason thereof."

At one of the proceedings here in Denver last summer, and it was almost as warm then as it is getting to be in this room, Mr. Ruth took the stand, and he complained, of course, that we interfered with him and said the things that you heard mentioned this morning. I asked him: "Mr. Ruth, don't you know that you can sell your machine and could sell your machine at all times subsequent to December 1917, nearly three years ago, to any licensee of Minerals Separation?" And he said, he didn't know anything about it. Strange, with our license agreement out, with this article of the Mining Congress written last year and extensively distributed, that he didn't even know he was free to sell his machine to whomsoever he wanted.

There is always one question involved, and I want to explain it, if I can, because it has been explained to me by the patent lawyers, and I will say that such examination as I have made of that particular matter confirmed the advice given. We are criticized because we were hesitant, up to a certain time, about giving our consent

to the use of, or permitting our licensees to use the K & K machine, or the Janney, and also because in the contracts we were negotiating, let us say with the Stimpson Equipment Co., or any of the others, we insisted that they should not sell their machine to any but licensees, and that they could not sell their machines to infringers of our process under penalty of, I believe, ten thousand dollars. Let me explain to you. It has been stated time and again that if a machine is sold by the owner or inventor to some one else, for the purpose if you please, of working a certain process which the machine is designed to work, and which process is covered by a patent which belongs to some one else, the inventor of the machine which is used to infringe the process becomes a contributory infringer. Now, that is as clear as can be, and that is why Minerals Separation, in view of the long extensive and expensive patent litigation it has had in this country, steadily since 1911, had to protect and guard itself, and it could not agree that a manufacturer of a machine designed to work its process could sell his machine to an infringer, and Minerals Separation was advised at that time to protect itself accordingly. Also, when Minerals Separation first came over here people did not cotton to its process with the regard and affection that a parent bestows upon a child. A number of people used it without success. We were rather anxious to make a success of the process in this country. Failure of our process meant failure to us, and we naturally husbanded and kept together everything that we had which we knew would work the process so that we could get and deserve the name and the reputation of being able to save from waste, metal values which theretofore had gone to waste. When, however, our reputation was finally established, and not the reputation, if you please, you gentlemen of the Mining Congress have sought to give us, but the reputation of having been responsible in a great measure for much of the success of the Anaconda Copper, the Inspiration, the Calumet & Hecla and others—when it was known we had something worth while to take under the license or to steal by infringing, when we had established the value of that which we claimed we had, we withdrew many of the restrictions that theretofore we had used and employed. Now, I do not think it of moment or important at all from the viewpoint of the present or from the viewpoint of the future, to discuss or argue with you gentlemen, or with your counsel, whether some of the restrictions that we had in the past were improper, or vicious or grievous, or any of the other adjectives used against us by counsel, in the Federal Trade Commission proceeding—these restrictive covenants are over the dam. If the Federal Trade Commission want to bring them in as proof of methods or conduct on our part in the past, strength to their elbow, say I, but I am here talking to the members of the American Mining Congress today of the situation as of today, and if anything that I say, can clear up or explain in your mind doubts which exist, doubts as to the policy pursued, doubts as to what your rights are, of course, I will be glad. I will certainly try to. I say to

the members of the American Mining Congress in connection with our license agreement, in connection with our patents, and in connection with anything we have, that the doors of the Minerals Separation have been open and are open to any member of the Mining Congress or the mining industry, or, for that matter, to anyone else, entering its doors in good faith whether to become a licensee or to get information respecting the license agreement or with respect to anything else. I know we have made various enemies in the past. Wherever I have been in the West I have seldom heard anything said pleasantly or kindly. There have been times when I have had the opportunity to talk over or explain our situation, and the reasons pro and con, where we have made a friend, and some of the witnesses, as I said to you before, who testified against us in this Federal Trade Commission hearing, seeing the light of day and having had explained to them the situation in plain, simple Anglo-Saxon, as to what was what, have honored us by coming to us and desiring to become licensees. I say "honored" because when you can make a friend of an enemy, when the method you pursue turns an enemy into a friend, because he believes you are right, I think it is something of a privilege.

For six hours the representative of the Alien Property Custodian and I went through the files almost as ominous looking as the blue records on the table. When he spoke and said something about the "oppression of the mining industry" I said that I would like some governmental agency properly functioning learn there was nothing to this charge of "oppressing the mining industry", and I said, as I say to you, "I have heard this until I am tired".

Fortunately, Mr. John Ballot put in writing the answer to that question two years ago and with your permission, because it is in evidence in the Federal Trade Commission proceedings, I would like to read what he said as showing "the attitude of Minerals Separation towards the mining industry". It is dated the 28th of September, 1918, before the institution by the Federal Trade Commission of its proceedings and written more than two years ago.

"In response to Mr. Kresel's verbal request for a short statement giving our side of the case, stating that he had so far heard only the representatives of the other side, I will endeavor to give a brief summary of the actual facts, which may help him in the investigation of the charge of the alleged 'oppression of the mining industry', which you tell me he has advised you he has been requested to make. I begin with a short historical sketch.

"Leaving out the question of title for the moment, it is an undisputed fact that we were the first to introduce the air-flotation process in this country.

"Air-froth flotation and its practical application were totally unknown before we introduced it.

"The gravity method, or what is commonly called the method of concentration by water, was the only commercial process in general use for dressing or concentrating the values from certain low-grade ores, until the introduction of the flotation process.

"In March or April 1911, one James M. Hyde, an engineer, who had been in our employ until February 1911, and who, during his employment with us, had been specially instructed in the practice and application of the air-froth flotation process, approached the Butte & Superior management and induced them to adopt the use of our flotation process and take the risk of disputing the validity of our patent in the courts. It would take too much space to go into the detail here of Hyde's record in this connection. We therefore refer Mr. Kresel for a full account of it to the Butte & Superior Supreme Court record. From the foregoing it will be seen that Mr. Hyde, a former trusted servant, was responsible for our first lawsuit.

"Lest it should appear that the management of the Butte & Superior Co. entered into an arrangement with Hyde in ignorance of the facts, and unmindful of the consequences of the unlicensed use of our flotation process, it should be said at once that we gave the Butte & Superior management due and timely notice of the true position and of our claims to the process and expressed our desire to meet the management in every reasonable way with a view to negotiating a satisfactory arrangement for the licensed use of the process. They, however, questioned our rights, refused to negotiate with us, and proceeded to use the process without license. Their adoption of this attitude forced us to seek relief in the only direction possible, and it also injured us in several ways:

"First, because of their inexperience, the process when installed and put in operation in their mill worked with indifferent success for a considerable time. The reports of their bad results were disseminated abroad with the consequence that other mine owners were deterred from adopting the process. For corroboration of the foregoing statement, we refer to the evidence given by Frank G. Janney, chief metallurgist for the Butte & Superior Co. in the Miami case. (Citations and references to Record and Exhibits omitted.)

"In time, we were successful in inducing ex-Senator W. A. Clark and Mr. M. N. Atwater to take licenses from us, erect plants and operate them under our supervision. The results were highly satisfactory and demonstrated that the best economical results obtainable by the process depended in great part on the installation of suitable plants and on proper operation by men acquainted with the process.

"Secondly, the fact that a most important group of mining interests, known as the Jackling-Hayden Stone interests, who besides controlling the Butte & Superior, also control or manage, among others, the well known great mines of the Utah Copper, Ray Consolidated, Chino Copper, and Nevada Consolidated companies, was disputing our title to the flotation patents made it well-nigh impossible for us at first, and for a considerable time to induce any of the outside mine owners in North America to adopt our processes under the license on any terms. I need not enter here into the history, duration, and cost of this Hyde-Butte & Superior and other litigations. Suffice it to say that two of the suits are still

sub judice. The present status, as I stated to Mr. Kresel, is that in the Butte & Superior case we have applied to the Supreme Court for a writ of *certiorari* for the purpose of getting a final adjudication as to the extent of our rights to air-froth flotation, on a patent already declared valid by that court."

I turn now to the complaints said to have been made by anonymous people that we are hampering the mining industry and preventing the output of metals. We feel at a disadvantage, which must be at once recognized, because of the difficulty to meet a vague undefined indictment of which no particulars are given us and no specific charges indicated; nor do we know the accuser, who appears to be hiding behind the veil of anonymity, apparently unwilling to come forward and make the charge openly.

While anxious to meet any charge and give all information, we are, of necessity, unable to give any definite reply or make any answer except in a general way; but we give the assurance that if our accusers will formulate definite charges we will undertake to reply in detail to every point raised or every charge made.

In the first place, we think we may safely put the so-called Jackling-Hayden Stone and Miami groups out of the discussion. They have no right of complaint. They and their shareholders have received large profits in distributions of proceeds earned for them by their infringing use of our process. By their own election they have brought it about that their action and their companies' interests are being dealt with by the courts of the land and until final adjudication nothing more need be said about them.

Even in their case, in which we have been most wronged, if the one pertinent question were asked: Whether we had in the past, or pending proceedings for final adjudication, done anything to restrain or hamper their production of metal, we could decidedly and without fear of contradiction declare that we have not done so either directly or indirectly.

We might have acted otherwise. We might have taken full advantage of our right, and legal position to issue injunctions and compel them to cease the unlawful use of our process or close down their plants unless they complied with our rights. We have, however, done no such thing. They have been left free to operate their plants as they would, so as to insure their securing the best results and largest output of metal, without any interference from us, and they have not been slow in distributing and so dissipating the enormous profits derived by them from the illegal use of our patents.

Now, as to the remaining mining interests, we have already stated that the other important mining groups are our licensees, together with many other smaller mining companies, numbering some 103 active and prospective producers. Those operating are doing so with great profit to themselves, and are using the process under best conditions to yield the fullest advantage without any hamperings or hindrances whatever.

There, then, remains to be considered such mine own-

ers as have been using our process without license, and others who have not adopted flotation at all. We believe there are some 450 such unlicensed users, and to many of those we have sent notices with schedules of rates of royalty (reference to exhibits omitted), informing them that we are prepared to grant them licenses at any time, upon their making adjustments for past unlicensed use of the process. Some have responded to our notices and have compromised for their past unlicensed use of the process and have taken out licenses, and so far as we know they are well satisfied. Others of the 450 unlicensed users have disregarded our notices and invitation. We have, however, so far done nothing to hamper their operations and profitable use of our processes, although they have arbitrarily taken our property and used it because its use brings them great profit out of what had been waste and loss before.

As we understand it, we are bound legally, to protect our rights, and were advised that it was our duty to send the formal notices to unlicensed users. Beyond sending these we have so far done nothing to restrain or reduce their output of metal. Even though legally we have the right to issue injunctions we have in no case taken such a course, although common justice demands that the unfair use of our property and unfair competition with our licenses ought not to be permitted to go on indefinitely.

Those who have so far not adopted flotation can at any time obtain a license from us, on request. It has been and continues to be our policy to meet every case fairly and squarely, taking into consideration the special conditions which obtain in each case. We have spent much time and thought in developing various schedules of royalty to meet general as well as special cases and classes of ores and metals, and we are always willing to discuss or consider special cases or suggestions.

I was asked what I thought should be done, and I will tell it to you. I think, perhaps, if the American Mining Congress undertook through its directorte, to appoint a committee of men in the mining profession, men of character—and you have so many—unbiased and judicially minded, and told them to take up with us, and we are always ready to take up and discuss and explain the various problems that they think are oppressive to the mining industry, we will be very glad to sit down with them, and we will be very glad to confer with them; and it may very well be that much in the way of misunderstanding and delusion will be dissipated. Go ahead with all your proceedings at the same time, if you want, I don't care, but I am thinking of something bigger and broader than litigation; I am thinking of something bigger and broader than success, either success for me, or success for the Mining Congress. I am thinking of the mining industry, which means much to Minerals Separation, and to which Minerals Separation means much. I am thinking that we should once and for all sit down in a calm, judicial, dispassionate way, determine what is right, and what is fair, and if that is done, truly the mining congress is an American Mining Congress.

The Geology of the Portland Canal District

By Victor H. Wilhelm

The Portland Canal mining district covers a portion of the Coast range extending from the head of Portland Canal up the Salmon and Bear rivers. The district is bounded on the west by the granitic uplift of the Coast range. The oldest formation in the Salmon River district consists of a series of volcanic tuffs and breccias, called, by R. G. McConnell, the Dominion Geologist, the Bear River series. This series is overlain by the Nass series of argillites and tuffaceous conglomerates, and is intruded by large sills and tongues of quartz-porphyry, which are intermingled with volcanic agglomerate. During the Jurassic period occurred the granitic uplift of the Coast range, coincident with and subsequent to which the whole area was intruded by a series of granitic and porphyritic rocks, in stocks and dikes, as spurs and offshoots of the granitic magma. Subsequently, during a period of readjustment, probably during the Tertiary period, the area of quartz-porphyry and breccia was sheared and mineralized by ascending solutions from the dying batholith. Subsequent to this primary mineralization, the entire district was intruded by small irregular dioritic dikes, which cut but do not interfere with the continuity of the mineralized shear-zones. The quartz-porphyry has been altered and silicified and has a marked schistosity, the direction of which governs the ore-zones. These consist of a shattered area filled with reticulating quartz veins and stringers. The metallic sulphides are disseminated through the quartz-porphyry as well as the quartz veins. Erosion throughout this area has been very great, and the primary sulphides outcrop on the surface, presenting the appearance of lenticular lenses or blankets of truncated orebodies.

The Premier mine, situated 14 miles north of Hyder, Alaska, in the Salmon River valley, is the only large developed property in this entire district. The orebody consists of a shear-zone in quartz-porphyry trending N. 80° E. and S. 80° W., with secondary mineralization along the fault-planes or step-faults bearing NE. and SW. High-grade ore occurs along this secondary fissuring and at the intersections of the shear-zone. The main orebody consists of irregular lenses within the highly silicified quartz-porphyry, and averages 1000 ft. in length and 80 ft. in width. A considerable amount of high-grade shipping ore, consisting mainly of argentite, has been found along the hanging-wall side of the shear-zone. Besides the shipping ore, the mine contains a large body of low-grade complex sulphide milling-ore contained mainly between the step-faults.

The Missouri group of claims, situated 17 miles north of the head of Portland Canal, in the Salmon River basin, consists of an immense residual sulphide orebody covering a surface of over 40 acres, being over 1600 ft. long, and in places over a thousand feet wide. The formation

consists of volcanic tuffs and scattered fragments of slate deposits, intruded by large masses of schistose quartz-porphyry. Numerous large dikes of fresh quartz-porphyry and granite coming from the large batholith of granite, which lies a few miles to the west, cross the area

THE 'BUSH' MINE, AS SHOWN ON THE MAP, IS THE SAME AS THE 'PREMIER'

and seem to have considerable influence on the orebodies. Diamond-drilling has shown this primary sulphide orebody to be a residual surface sulphide zone. The following is an analysis of an average sample of this ore: gold, 0.03 oz.; silver, 2.3 oz., lead, 2.5%; zinc, 5.2%; copper, 0.6%; iron, 14%; insoluble, 59%. This indicates galena 2.5%, blende 7.6%, chalcopyrite 1.55%, and pyrite 29.3%. Simple concentration gives the ratio of 2.7:1.

On a slide, adjacent to the Salmon River glacier, on this property, there is over a million tons of ore of the above grade already broken. This property would not need depth to make a mine because of its large surface area. On the E Pluribus and Laura claims, north-east of the primary low-grade sulphide orebody, there exist some high-grade surface showings. These orebodies occur in lenses along step-faults at right-angles to the general trend of the shear-zone. The Joker claims on the east show the same characteristic high-grade surface ore-lenses dying out at a shallow depth.

The Spider group, under bond to the Algonian Development Co. of Brussels, Belgium, situated three miles north-east of the Missouri group, consists of a shear-zone in which small high-grade veins intersect an older group of large low-grade quartz veins in an intrusive mass of augite-porphyry. Over 700 ft. of lateral development along one of the small veins has exposed several shoots of shipping ore, and considerable enrichment is looked for at the intersection of the shear-zone with the large low-grade quartz veins. The ore consists of a complex sulphide, analysis of which is as follows: zinc 9.37%, silica 62.25%, copper 2.92%, lead 5.2%, silver 1.98%, iron 5.2%, aluminum and sulphur 13.68%. The orebodies seem to have considerable persistence in depth, and will probably develop into a small mine. This property will ship 500 tons of high-grade silver ore this winter.

The Bear River valley in this district was the scene of a boom about ten years ago, and several properties of decided merit were developed in the slate area. At that time the district was more or less discredited by the exploitation of a few properties of doubtful merit. The orebodies consist of large irregular complex sulphide orebodies in lenses or shear-zones in slate. The development of ore-reserves in ground of this character is very difficult. At the present time there is considerable mining activity in the breccia and tuff area of the Upper Bear River valley. The orebodies consist mainly as large lenses of chalcopyrite containing gold and silver. The surface exposures are large, and with continuity in depth the properties would be able to develop immense ore-reserves at slight cost. The Comet, Rufus, and George Copper are the principal properties. The Red Top in this district has a large outcrop of galena in the same formation. The properties are fairly accessible, owing to the fact that the dilapidated line of the Canadian North-Eastern railroad runs up the Bear River line for a distance of 14 miles.

Provided that a considerable tonnage is developed, the Portland Canal district offers no great difficulties to successful mine operation. The mineralized area is from 12 to 20 miles from tide-water, and railroad construction would not be difficult. The area below the 2500-ft. line of elevation is densely timbered, and summer water-power can easily be developed for from five to seven months, but storage-basins for the development of winter power are scarce. The rich ores can be smelted, but the low-grade ores will require considerable experimentation before a successful milling process is developed.

Permissible Explosives

An explosive is called a permissible explosive when it is similar in all respects to the sample that passed a certain test by the Bureau of Mines, and when it is used in accordance with the conditions prescribed by the Bureau. But even the explosives that have passed these tests and are named in this list as permissible are to be considered permissible explosives only when used under the following conditions:

1. That the explosive is in all respects similar to the sample submitted by the manufacturer for test.
2. That detonators—preferably electric detonators—used are not less efficient than those prescribed, namely, those consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate (or their equivalents).
3. That the explosive, if frozen, shall be thoroughly thawed in a safe and suitable manner before use.
4. That the quantity used for a shot does not exceed 1½ lb., and that it is properly tamped with clay or other non-combustible stemming.

After an explosive has passed the required tests and its brand name has been published in a list of permissible explosives, it is not a permissible explosive if one or more of any of the following conditions prevail:

1. If kept in a moist place until it undergoes a change in character.
2. If used in a frozen or partly frozen condition.
3. If used in excess of 1½ pounds per shot.
4. If the diameter of the cartridge is less than that designated 'smallest permissible diameter'.
5. If fired with a detonator or electric detonator of less efficiency than that prescribed.
6. If fired without stemming.
7. If fired with combustible stemming.

Moreover, even when all of the prescribed conditions have been met, no explosive on the permissible list should necessarily be considered as being *permanently* a permissible explosive, for the Bureau reserves the right, on fuller information concerning the conditions that lead to safety, to revise this list; but any permissible explosive when used under the prescribed conditions may properly continue to be considered a permissible explosive until notice of its withdrawal or removal from the list has been officially published, or until its name is omitted from a later list published by the Bureau of Mines.

No GOLD was produced from quartz or placer mines in North Carolina in 1919, and at only one deep mine, that of the Rich Cog Mining Co., at Eldorado, Montgomery county, was any development work done. The value of the gold produced in North Carolina during the period 1799 to 1918 was \$23,628,413. In 1915 the recovery of gold amounted to \$172,001, but in 1918 it decreased to \$1631, which, with 17 oz. of silver, was derived from placer mines or old mill clean-ups. Increased costs of mining and milling the low-grade gold ores and gravels have made operations unprofitable.

California's Metal Output in 1920

*The outstanding and unprecedented feature of metal mining in California in 1920 was the closing down of a great number of the largest gold and copper mines, and the conditions generally have been decidedly adverse, particularly in the Mother Lode region, where some of the mines that were once among the largest in the State have stopped work, several of them permanently. Both the Kennedy and the Argonaut mine, at Jackson, Amador county, were closed, mainly on account of trouble with fire and water. Other lode mines that stopped work were the Keystone, Utica, Gold Cliff, Eagle-Shawmut, and Tightner. The smelters of the Mammoth Copper, Mountain Copper, and Penn Mining Co., usually among the largest producers of copper in the State, remained shut-down during 1920, and the Walker Copper Co. closed late in the year. The Afterthought Copper mine, in Shasta county, was active for the first two months, when both mine and plant were closed. Another feature of the year was the restriction of the supply of power by hydro-electric companies in the fall, which affected the deep mines of all classes as well as the dredging companies. For lack of this usual power some mines had to close altogether and others were compelled to restrict operations. When the first fall rains commenced, in October, the supply of power was at once restored. The hardships suffered by the gold miners in the foothill and mountain counties have partly depopulated towns and camps and even counties. Numerous mines are being allowed to fill with water, and some reduction plants have been virtually abandoned.

The labor available in the mining regions of the State is reported to be still unsatisfactory, and its high cost and inefficiency have been the principal causes of the closing down of many large mines and of the curtailment of operations in others, although other high costs have contributed to reduce production. Prospecting has been almost stopped in the older mining regions, and very few large mining enterprises have been started. In fact, it is difficult or almost impossible to obtain capital for gold mining, as few miners are making a profit. Some large producers are unwilling to push production and development and pay the consequent war income tax, so they are only keeping the mines running. The force of men engaged in all kinds of mining work has been cut down. The cost of producing gold has been steadily rising for several years, until it nearly prohibits all profit.

Without the dredging industry of California, gold mining in the State would be at low ebb, for the adverse conditions have more strongly affected lode mining than placer mining. Of the total gold produced in the State in 1920, 52% was obtained from deep or lode mines and 48% from placers. The dredges are producing 96% of the placer gold, or 46% of the gold output of the State.

*Advance estimates by Charles G. Yale, San Francisco office of the U. S. G. S.

There seems to be a small continuous decrease in the percentage of gold produced by the deep mines and a corresponding increase in the percentage produced by the placers. Of the gold produced by deep mines the larger proportion is derived from silicious ore, but some is derived from copper, lead, and zinc ores. The dredges have been increasing their proportion of the total output of gold, but the hydraulic, drift, and sluicing mines are steadily decreasing their proportion. Since the dredges began work in California, in 1898, they have dug out about \$120,000,000. Though some of the smaller and more isolated placer fields have been worked out, new placers have been found, and the larger fields, except that at Oroville, are showing an increased output annually. About 45 dredges, some of the very largest size, are now in operation in California.

Although gold has been mined in California for more than 70 years, it is still produced by 32 of the 59 counties of the State. Yuba county, in the early days famous for its hydraulic mining and afterward abandoned for more than 30 years as a mining field, is now the leading gold-producing county of the State, its output exceeding by over a million dollars per year that of the most productive deep-mine county. This revival and increase of production is due entirely to dredging, which produces 99% of the gold output of the county. The ground now worked by the dredges is not only covered with debris from former hydraulic mining, but is too low and carries too little gold to be mined profitably on a large scale by any other system than dredging. A few new dredges were set to work in 1920 on fields in California outside of Yuba county, and several stopped work. One of the new operations is that of the Yankee Hill Dredging Co., in Stanislaus county, between Oakdale and Knights Ferry. Another, operated on a new plan—a 'dry-land' dredge—is in the Noce placer holdings, in the eastern part of Calaveras county.

The output of silver from mines in California was about 1,538,660 oz. in 1920, an increase of 431,471 oz. over that in 1919. This increase is somewhat surprising in view of the fact that the largest copper smelters in the State were closed down during the year, for a considerable part of the silver produced is usually obtained from copper ores. But there was an increase in the output of lead and lead-silver ores in southern California, with consequent increase in silver from those sources. Moreover, the California Rand mine, in San Bernardino county, continued to ship high-grade ore during the year, making a material increase over its normal output.

The estimated output of copper in California in 1920 was 12,934,900 lb., as compared with 21,732,507 in 1919, a decrease of 8,797,607 lb. The Mammoth Copper Co. and the Mountain Copper Co., of Shasta county, and the Penn Mining Co., of Calaveras county, kept their smelters closed throughout the year, and the Walker Mining

Co., of Plumas county, stopped production for several months. These facts account for the decrease in the output of copper in 1920 in California, for the mines mentioned are among the most productive in the State. Smaller properties throughout the mining region also stopped producing copper ores, owing to the low price of the metal and adverse general conditions.

The estimated output of lead in 1920 is 5,071,600 lb., an increase of 1,503,333 lb. over the output in 1919. This increase is due entirely to the production of one mine in southern California that reported no output in 1919. Moreover, a number of lead and lead-silver properties, mainly in San Bernardino and Inyo counties, began or increased production in 1920. Nevertheless the output of lead in California is still far below the normal, as that in 1918 was over 13,000,000 pounds.

The zinc output of California in 1920 is estimated at 1,522,500 lb., or 1,099,029 lb. more than in 1919. Zinc was produced at only a few mines in the State, all in Inyo county.

Among the newer operations in hydraulic mining in California is the completion of the debris-restraining dam of the Elephant hydraulic mine, near Volcano, Amador county. This dam is 30 ft. high and 425 ft. long. Not many new dams of this kind were built in California in 1919, as few hydraulic mines have been opened and equipped. The old Curtz Consolidated mine, at Markleeville, Alpine county, has been sold, and the new owners are repairing the old workings and arranging to resume operations. The Monitor, also in Alpine county, has been shipping some ore. A new 10-stamp unit has been added to the milling plant of the Carson Gold Mining Co., in Calaveras county, giving it a capacity of 15,000 tons per month. The old Cherokee mine, near Oroville, Butte county, once a famous hydraulic property, is to be re-opened. The channel of this mine runs under Table mountain. The El Dorado Exploration Co., Eldorado county, has discarded its steam-power plant at both mine and mill and has installed an electric plant. The North Star Mines Co., at Grass Valley, has stopped the use of its costly tramway and uses an electric locomotive and self-dumping cars to remove mill tailing to a new storage basin, built to receive it. The old Delhi Mining Co., which owns extensive water-rights on the middle fork of the Yuba river, has put in a new hydro-electric power-plant, partly for its own use but partly to supply power to the Pacific Gas & Electric Co. for general use. At Meadow Lake, Nevada county, a mining camp that was virtually abandoned for 25 years, a cyanide plant has been put into the Excelsior mine, and some of the other old mines will be re-opened. The California Rand silver mine, in San Bernardino county, the most productive silver property in California, continued during 1920 to make shipments of high-grade ore to the smelter on San Francisco bay. The Globe and Chloride-Bailey mines, near Dedrick, Trinity county, have been purchased by New York men and are being re-opened. The Balaklala Copper Co.'s smelter at Coram has been torn down, and some of the steel and other ma-

terial obtained from it is being used in the new plant of the Shasta Zinc & Copper Co. at Winthrop, in the Bully Hill region. The Mountain Copper Co. has built a 600-ton plant for crushing pyritic ores from the Hornet mine. Although the smelter of this company has been closed throughout the year, development work has been continued in the mines. The Twenty-One Mining Co., at Alleghany, Sierra county, has sold its mining property to the Sixteen-to-One Mining Co., thus ending a long litigation. The Harvard mine, Tuolumne county, long owned by Boston men, has been sold to John Ferguson and associates, of Berkeley.

Copper in 1920

The smelter production of copper from domestic ores during the year 1920 is estimated by H. A. C. Jensen, of the U. S. Geological Survey, to be about 1,235,000,000 lb., compared with 1,286,000,000 lb. for 1919. The production of refined copper from foreign and domestic ores for the year was about 1,573,000,000 lb., which is approximately 195,000,000 lb. less than for the year 1919. The apparent domestic consumption was about 910,000,000 lb.; in 1919 it was 877,000,000 lb. The stocks of raw and refined copper at the end of 1920 were about 874,000,000 lb., which represents a decrease of 30,000,000 lb. from those held at the end of 1919. The total imports of raw and refined copper for the ten months ending October 30, 1920, according to the Bureau of Foreign and Domestic Commerce, were 407,437,515 lb. Exports of copper for the same period were 543,695,851 lb., compared with 516,627,775 lb. for the entire year 1919. The continued decreased production, the large stocks, and the low domestic consumption were due entirely to the generally depressed conditions of industry throughout the world, which did not permit the absorption of as great quantities of copper as had been hoped for. Low exchange and the great stocks of scrap and secondary copper available both in the United States and abroad also decreased the demand for new copper. The salient features of the copper industry during 1920 were a small hesitating demand, decreased production, continued small exports, particularly during the last half of the year, and labor troubles.

THE total value of the mineral production of Alaska increased from \$19,620,000 in 1919 to \$22,070,000 in 1920, according to estimates by Alfred H. Brooks of the U. S. G. S., just made public. This brings the value of the total mineral production of the Territory up to \$460,000,000, over half of which is to be credited to the last decade. The apparent prosperity of the Alaska mining industry during the year is due solely to the increase in the output of copper from 47,220,000 lb., valued at \$8,783,000, in 1919, to about 71,000,000 lb., valued at \$12,400,000, in 1920. Alaska has now produced 616,200,000 lb. of copper, worth \$127,000,000. As in past years, the only mines that made a large output of copper were those controlled by the Kennecott Copper Corporation, the total production of ore being 330,000 tons.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

PLANS FOR INCREASED PRODUCTION BY DREDGING.

ASPEN.—Samples of ore from the Park tunnel (said to be polybasite) have attracted much attention. The ore assayed 13,092 oz. silver. The vein is four to six feet wide and, aside from the rich streak, samples 241 oz. silver per ton. The strike was made in the Best Friend incline on Sam Houston ground and is developed through the Jenny Lind tunnel. Development of the new orebody in the Hope tunnel continues and, with the compressor connected with a motor recently secured, cross-cutting to the hanging wall and foot-wall of the vein will be completed and the width of the shoot proved. Supplies for the winter and spring have been taken into the Hurricane company's camp, where work on the lower tunnel of the Etcetera claim is being pushed. The tunnel will cut the orebody where ore was discovered before the miners were driven out by water. Connection will be made by a raise and the shaft workings drained.

BRECKENRIDGE.—Last year's recovery of gold by the dredges, which totaled \$500,000, will be exceeded this year if plans of the dredging companies are carried through. More properties are active than for many years past, and among these are the Dunkin and Price mines on Nigger hill; Quandary Queen, Mount Helen; Iron Mask, Missouri, Brooks Snider, and Deep Shaft, Shock hill; Standard, Gibson hill; June Bug, Gibson gulch; Warriors Mark, Maximus, Laurium, and Molly B. on Yuba Dam flat; Billie Junior, and Wellington. The mills of this company closed down in November, due to low zinc prices, but development continues. During 1920 the Wellington stockholders were paid \$100,000 in dividends, a total to date of \$2,000,000.

CENTRAL CITY.—The Midwest Mining & Milling Co. is making progress with mill construction at Black Hawk and the Iron City mill of the company is operating at profit and turning out high-grade concentrate. Work continues in the Midwest tunnel and a 12-in. streak of smelting-grade ore has been opened in the Peru. Work has been resumed on the National mine by E. S. Moulton and associates and ores containing gold, silver, and copper are shipped to and treated at the Rocky Mountain concentrator at Black Hawk. Machinery at the Coeur D'Alene and Isabel mines has been overhauled preparatory to the resumption of work by the National Finance & Holding Company.

CRIPPLE CREEK.—Eight sets of lessees on the property

of the Mary McKinney company, three in the main shaft, three in the Anaconda, and two sets in the Howard-shaft workings are mining and shipping medium-grade ore to Golden Cycle mill at Colorado Springs. No work is being done on company account. Cresson is maintaining production at 8000 tons monthly and building up its treasury reserve. Two shifts are employed and 120 miners are kept on the payroll.

The El Paso Extension Corporation is installing an electric hoist at the Rittenhouse shaft, Gold Hill, and has laid and connected an air-line with its compressor at the Index shaft, preparatory to development of the low-grade ore on the property.

DURANGO.—Ore from the Rico Wellington mine, averaging \$20 per ton, is being shipped at a profit to the Durango smelter as the result of a low freight-rate of \$2.50 per ton, recently put in effect. A new orebody sampling 18 oz. silver and 7 to 10% lead was recently entered and is now under development. The company last month also shipped to the smelter 500 tons of pyrite that averaged 42.5% iron.

IDAHO SPRINGS.—The Gem company has installed a 75-hp. electric hoist at the Freighter shaft, and development is under way. Machinery formerly in use at the Carr mine in Gilpin county has been purchased by the Fraction management and is being removed for installation at the Clear Creek property. A new orebody has been opened and shipments will start as soon as the hoist is in operation. The Roosevelt company at Alice is installing a new stamp-battery, while miners are breaking ore in two headings of the tunnel. A tram from the tunnel to the mill is under construction.

MICHIGAN

TAXES ON MINING PROPERTY ARE BURDENSOME.

HOUGHTON.—The mines of the Lake Superior copper region are now paying their 1920 taxes. The tax roll in Houghton county for 1920 is \$1,910,351, and it is estimated that 85% of this will be paid by the mining companies. The tax burden is considerable at this time owing to the drain on treasuries at a time of depressed metal market. The tax is based on an assessed valuation of \$91,878,050. There has been a heavy increase in mine taxes since 1916 in keeping with advancing costs, and from \$200,000 to \$300,000 has been added each year. The tax cost is particularly burdensome to companies

only in an exploratory stage. As an illustration, Mayflower has just paid approximately \$22,000 in taxes, and yet it has not produced a pound of copper. The tax account actually is equivalent to an operating expense of four months. Other mines that are not operating, but whose shares have remained comparatively high, also are hard hit. In determining the valuation of mines, the market price of the stock is the basis and the average price of the shares for the year is taken as the figure. The quotation at the close of the market every Monday for the 52 weeks of the year is totaled and the mean is the average value. The method often has been criticized, but as a matter of fact no better system has been devised and it has been upheld by the Supreme Court of Michigan. It is considered out of the question to assess a mine according to its physical valuation. Under this method, while the mines have been hard hit in 1920 taxes, assessed valuations will be considerably lower this year, as they will be based on the relatively lower market for all shares in 1920.

Removal of shaft pillars in No. 4, Wolverine, is yielding ore averaging 17 lb. of refined copper per ton. The 'rock' is selected, only that rich enough to stamp being mined. The pillars that are being taken out from the bottom of the mine upward to the 28th level, are fairly rich and uniform in copper content. The work of removing pillars has not yet started in No. 3, in which a considerable amount of ground remains to be stoped out in the old workings in the upper levels. Both drifts and stopes will be widened. There are wide stoping areas on practically every upper level that will yield rich ground and require a number of years to exhaust. Wolverine is hoisting 900 tons of rock daily and employing as many men as it can handle underground. Present costs, exclusive of taxes, are 15c. per pound.

Mohawk, which has been adding underground men from time to time, now has an efficient force, and production has reached 2350 tons per day. In No. 1 shaft, two drifts are being pushed south from the 23rd and 24th levels to connect with No. 4 shaft. The 23rd level is 500 ft. from No. 4 and the 24th is 1100 ft. The purpose of these connections is to extend the electric tramming system to No. 1 shaft, which will result in a reduction of tramming costs. Electric tramming is now in use only in No. 4. Considerable ground remains to be worked out of No. 2 and 3 shafts, both of which were abandoned some years ago, but this work will not be undertaken until all of the working shafts reach their limit in depth. There are stopes to be widened out, arches and supports to be cut away, and levels to be driven to the foot and hanging walls before the final operation of removing the shaft-pillars. The same process ultimately will follow in No. 1, 4, 5, and 6. Four heads are now in operation at the Mohawk mill and two in the Wolverine. With the new electric pump in service at the mills, a saving of 25% in fuel costs has been effected. The pumps, which supply the water for the mills, are operated by a turbine which is driven by exhaust steam from the stamp-heads.

NEVADA

CONSOLIDATED COPPERMINES STOPS WORK TEMPORARILY.

ELY.—The Consolidated Coppermines company has discharged the 60 men employed and has stopped operating, supposedly because of the low price of copper and general conditions. Last summer this company had decided to build a 2500-ton smelter and concentrator, but this work has been indefinitely postponed. There is estimated to be 20,000,000 tons of 1.33% porphyry ore, 200,000 tons of 3% heavy-sulphide ore, and 500,000 tons of 7% oxidized ore in the various workings. The Ward lead-silver mine, 12 miles south of here, has been closed because of the low price of lead. The 30 miners employed have been discharged and no further attempt will be made to operate the mine until the metal market improves. Shipments had been made for several years at a rate of 250 to 500 tons monthly and it was announced recently that the rate was to be increased to 1500 tons and then to 3000.

TONOPAH.—The Clifford silver-gold mine, credited with a production of \$500,000 since it was discovered 15 years ago, has been bonded by the Clifford estate to New York interests. The mine is 40 miles north-east of Tonopah, and during the years it has been worked by the Cliffords it has produced remarkably rich ore, most of which was treated in a small mill on the ground. In recent years little work has been done because of a disagreement among the heirs. The mine consists of 14 claims, developed through two 200-ft. shafts. Settlement sheets from the Selby smelter show, among others, the following shipments: 426 lb. concentrate assaying 7569.16 oz. silver and 38.84 oz. gold per ton; 1640 lb. ore of a net value of \$1742.76, figuring silver at 59c.; 400 lb. concentrate of a net value of \$1435.30, with silver at 48¢; 142½ lb. concentrate assaying 14,228.37 oz. silver and 226.12 oz. gold per ton. There are exposed many good shoots of medium-grade ore, including a 3-ft. width of \$38.90 ore and a 9-ft. width of \$22.40 ore. There is said to be enough \$20 to \$30 ore exposed to warrant the erection of a mill, and the holders of the bond plan to develop the mine on a good scale. Among other improvements it is planned to lay five miles of 6-in. water-pipe. The ore is free-milling.

DIVIDE.—The Rosetta, in the extreme southern part of the district, has officially reported an important find of \$20 to \$60 ore in a cross-cut driven east at a depth of 300 ft. Ore of this grade, the average value being unknown, has been penetrated for 12 ft. There have been no new developments on the 800 or 1000-ft. levels of the Tonopah Divide, where drifts are being continued south-east to reach under ore-shoots on the upper levels. A pipe-line has been completed from the Gold Reef shaft and water will soon be pumped from this source at an estimated saving of \$5000 yearly over the cost of hauling from Tonopah. The Gold Zone continues shipping from the 700-ft. level at a rate of 500 to 600 tons per month. This ore is coming from a stope and from this work is to be done to determine definitely whether the ore on the 700-

ft. level is in a fissure parallel to the main Tonopah Divide vein or is in that vein, displaced by faulting. When this has been determined it is planned to sink a winze from the 700-ft. level in the ore-shoot, which is 25 ft. long and 4 ft. wide in a vein 20 ft. wide.

MANHATTAN.—A 6-ft. width of ore has been entered 350 ft. from the shaft in the west cross-cut on the 800-ft. level of the White Caps. This ore is far east of where the main orebody should be entered at this depth. The cross-cut is being continued by two shifts of miners working under contract. In addition to this work two cross-cuts are being driven on the 500-ft. level.

HAMILTON.—Ed. Wilson and Ole Johnson, working the Great Valley silver-lead mine under lease, are hauling a carload of ore to Kimberley on the Nevada Northern railroad for shipment in the spring. Wilson and Johnson have worked the mine for the last four years, making occasional shipments to the smelter at Midvale, Utah.

PIONEER.—The Mayflower mill, in which many alterations and improvements have been made since it and the mine were taken over by the Tobin management, is being tested on low-grade ore from the main workings and the Starlight, into which a cross-cut is being driven with three shifts of miners.

STONEWALL.—Gordon M. Bettles, manager of the Yellow Tiger, estimates that after the improvements now being made have been completed at the mine and at Ralston station on the Tonopah & Tidewater railroad a saving of 40% in previous costs will be made. The company is building at the station an oil-tank that will hold a carload. This should result in a saving of seven cents per gallon and give a uniform grade of oil. Work will be resumed soon in the Sterlag tunnel.

UTAH

DURING 1920 PARK CITY AND EUREKA DISTRICTS BOTH EXCEEDED PRODUCTION OF 1919.

SALT LAKE CITY.—Ernest Bamberger, general manager for the Ontario Silver Mining Co., W. Mont. Ferry, managing director for the Silver King Coalition Mines Co., and Imer Pett, general manager for the Bingham Mines Co., were representatives of Utah lead producers at the meeting of the Ways and Means Committee of Congress on January 12, 13, and 14 when the question of a tariff on lead was argued. The Utah delegation presented data to substantiate the claim that lead producers in this State cannot continue to operate unless a protective tariff is imposed on the metal. During 1920, the lead output of the State was about 134,000,000 lb., with an estimated value of \$10,939,000, so that local lead producers are naturally anxious to see the industry protected. The value of the gold, silver, copper, lead, and zinc produced in Utah during 1920 is estimated at about \$46,000,000 by Victor C. Heikes, of the U. S. Geological Survey, as compared with a value of \$45,169,328 for 1919. The output of gold and copper decreased considerably, while that of lead and zinc increased, with the silver production practically the same for both years.

PARK CITY.—During 1920, ore shipments from this district totaled 99,864 tons, as compared with 75,623 tons for 1919. The increase was due to the high prices of silver and lead prevailing during the early months of 1920, and to the opening up of several high-grade stopes in various mines. Had it not been for the slump in the price of lead during the latter months of the year, shipments would have been larger. The Judge electrolytic smelter produced 2323 tons of premium spelter during 1920, as compared with 3667 tons during 1919. The plant was closed down on November 1, due to the unsatisfactory condition of the zinc market and the increase in electric-power rate.

Preparations are under way for the installation of a large electric pump on the 2000-ft. level of the Ontario

MAP OF NORTHERN NEVADA

mine, and it is estimated that about two months time will be required to complete the work. The capacity of the new pump will be 15,000 gal. per minute. The pumps now in use on the lower levels will not be disturbed, and they will be kept in operation when necessary. The management states that there is no intention at present to sink from the 2000-ft. level.

EUREKA.—Ore shipments from this district for the year 1920 totaled 7397 cars, or approximately 296,000 tons, as compared with 6921 cars, or 276,000 tons, for 1919. As was the case with other silver-lead camps, production was pushed to the limit during the early months of the year, but during the latter months, owing to the decline in metal quotations and increased freight-rates, shipments were curtailed. During April and May, owing to the switchmen's strike, production was curtailed at all of the leading properties, owing to embargoes placed on shipments by the Salt Lake Valley smelters.

The concreting of No. 2 shaft at the Chief Consolidated mine was completed December 31. Drifting has been started on the lowest level at the property—the 1900. The shaft is the first in this State to be concreted, and while the expense has been heavy, the management feels

that the cost of repairs will be moderate as compared with a timber-lined shaft. During 1920, the Chief Consolidated established a new high record in the matter of production; 1948 cars of ore were shipped, as against 1299 cars for 1919.

It is reported that work will be resumed by the Knight interests at the Tintic Drain Tunnel property early in the new year. The tunnel is now in a distance of over a mile, and work was suspended owing to the financial stringency, some months ago. It is stated that a raise will be driven through to the surface, at a point near the face of the tunnel, and that following the completion of this work, regular driving operations will be resumed. The raise to the surface will be for ventilation purposes.

The work of enlarging and re-timbering the shaft at the Eureka-Standard property in the eastern part of the district is under way; the old single compartment shaft will be enlarged to standard size, and heavier equipment will be installed to permit further sinking. The bottom of the shaft is now at 550 feet.

Stoping has been started at the Eureka Mines property from a 10-ft. face of ore, which is a continuation of the stope mined in the Gemini property, from which shipments were made averaging 30 to 35 oz. silver and from 20 to 40% lead. At the Eureka Mines, the ore is being taken from just below the 940-ft. level, according to Jackson McChrystal, manager.

ALTA.—Four snowslides occurred upon the properties of the Emma Silver Mines Co. and the Michigan-Utah Mining Co. on January 5. One of the slides passed over several bunkhouses of the Emma company, doing but little damage. Another slide carried away the loading-station of the Michigan-Utah company, and damaged the trestle. No one was injured. Development work at the Columbus-Rexall property is proving that the mineralization in the two main fissure systems is persistent and rich, according to C. M. Evans, superintendent. Exploration work is being confined to the No. 8 and No. 10 fissure-systems. A drift has been run along fissure No. 8 for about 100 ft. At the top of the drift, five feet of high-grade ore has been cut. Both of the fissure systems make into virgin territory, and the prospect is good.

BIG COTTONWOOD.—The main working adit at the Big Cottonwood mine is now in a distance of 3268 ft. and for the last 100 ft. has been driven through a favorable formation, according to C. E. Robertson, secretary-treasurer. Stringers of sulphides and carbonates have been passed through. The objective of the adit is the Copper King fissure, estimated to be about 400 ft. distant. It is possible that the fissure has taken a slight dip in the direction of the tunnel, in which event the distance will be even less.

WISCONSIN

REVIEW FOR DECEMBER.

December witnessed the utter demoralization of the zinc-mining industry of south-west Wisconsin. In December there were no official zinc-ore quotations. When the

State Railroad Commission granted the petition of the Interstate Light & Power Co. to advance power-rates 31% some of the larger producers immediately decided to shut-down. The Mineral Point Zinc Co. ordered its entire list of producers in the field, including the famous Coker, Hoskins, Penna-Benton, and Black-Jack mines, shut-down, throwing 600 men out of employment. At the company's plant, in the city of Mineral Point, working schedules were reduced from seven days weekly to five days. A supply of raw-zinc concentrate on hand when the mines shut-down enabled the magnetic-separating plants and the sulphuric-acid works to continue, but as soon as this supply of raw ore, which furnishes the base for the manufacture of acid, has been treated the entire works will suspend. A few other mines have followed the example of Mineral Point.

On the other hand, at Platteville the Block-House Mining Co. operated steadily all month, selling but three cars of high-grade separator blende. It is said no shut-down is contemplated here. The two mines of the Frontier Mining Co., of Indianapolis, the Middie and Bull Moose, ran steadily on full-time schedules and by the close of the month had a reserve of 6500 tons of zinc concentrate, costing \$115,000. The Rodhams mine, a neighbor of the Frontier mines, observed the same program. The mines of the Wisconsin Zinc Co. were kept in operation all month. The first part of December found the company marketing green concentrate with the Mineral Point Zinc Co., but this expedient was soon terminated and the company's big all-steel magnetic separating plant at New Diggings, idle since August 1, was again heated up and green ore was being brought up to standard commercial premium-grade blende. The mines of the Steel & Tube Co. of America were all kept in operating shape through December, due to the fact that raw zinc ore is essential to the requirements of the company's acid plant at Cuba City.

In smelter circles depression was as much evident as in mining, for the Illinois Zinc Co., at Peru, closed down its zinc, acid, and sheet-mills as well as its coal mines, throwing 1000 men out of work. This smelter has been for many years one of the best buyers of Wisconsin zinc in the district. The Matthiesen & Hegeler Zinc Co., another large buying concern of Wisconsin zinc ore, sold its plant to the Schwab interests. It was said this transaction was the aftermath of a clash between DuPont and Ford interests, in which the former sought to embarrass the automobile manufacturer and prevent the purchase of materials essential to Ford. At any rate, B. Lissinger & Co., of New York, come into control of the smelter at LaSalle, also a buyer of Wisconsin zinc ore since 1879. Zinc operators here regard the passing of the M. & H. Zinc Co.'s smelter into Schwab's hand as a good omen for the zinc industry, in that it will result in the stabilizing of zinc-mine products. Whether they are correct remains to be seen, but it is known that representatives of the LaSalle smelter have intimated that they will require Wisconsin zinc ore in quantity.

Lead-ore offerings for December were stationary at

\$47.50 per ton. Shipments were almost nil, less than 100 tons going to smelters during the month. This came from the Benton district. There were no shipments of iron pyrites, and only a small quantity of carbonate-zinc ore was marketed. The reserve of zinc ore of all grades in the field at the close of December amounted to more than 15,000 tons; of lead ore 3000 tons; iron pyrite, 30,000 tons; and carbonate-zinc ore, 500 tons. The gross recovery of milled ore for the month amounted to 11,503 short tons; net deliveries to smelters, 1533 tons, all of which came from the National Zinc Ore Separators at Cuba City, except four cars which were shipped from the

each succeeding year. The bulk of the gold production of British Columbia and Yukon Territory passes through this office. A telegraphic message from Alice Arm states that the Dolly Varden mine has been closed, and that the men had to walk the 18 miles from the mine to tide-water through deep snow. The cause for the closing is not known. It was the intention of the Taylor Mining Co. to have retained from 80 to 100 men on the payroll during the winter. It is supposed that some difficulty has arisen with the men.

STEWART.—H. A. Guess, managing director of mines for the American S. & R. Co., has instructed the Riblet

CAR-DUMPER AT THE ARTHUR MILL, AT GARFIELD, UTAH

Block-House mine, in the Platteville district and sold to the American Metal Co. Where ordinarily 5000 miners find employment, less than 1000 men were engaged at the end of December. Prospect work with drills dwindled to the lowest level known to the field in years. Building operations were brought to an abrupt halt all along the line.

BRITISH COLUMBIA

TRANSPORTATION FOR PREMIER MINE ORE.

VANCOUVER.—The Dominion government assay-office in this city reports that during 1920 the total number of deposits of precious metal received was 1348, valued at \$2,499,229, against 1391 deposits, valued at \$3,547,525, in 1919, and 1358 deposits, valued at \$4,099,595, in 1918. It will be noticed that the number of the deposits remains fairly even, but their value has shown a marked decrease

Tramway Co., of Spokane, to make an investigation of the transportation conditions at the Premier property and prepare estimates for an aerial tramway between the mine and tide-water. The working tunnel is about 1400 ft. above tide-water; 900 ft. of rise occurs in the last three miles to the mine. Since the heavy rains of last summer it has been found practically impossible to keep the road in repair, and, unless frosts harden the road considerably, it is feared that it will not be possible to ship the quantity of ore that was hoped during the winter. The ore is being culled more closely, and some 700 tons of high-grade that is expected to average above \$500 per ton is ready for shipment, while a large amount of medium and low-grade ore awaits the completion of the combined concentration and cyaniding plant. Construction work on the mill is progressing as rapidly as material arrives at the mine.

ONTARIO

POWER SHORTAGE EMBARRASSES MINING COMPANIES AT PORCUPINE.

PORCUPINE.—The available supply of electric power for the mines is about 4000 hp., and this limit is not likely to be exceeded before spring. It is being allotted to those consumers who have contracts with the power company. The Hollinger Consolidated receives about 2000 hp., which, combined with 1400 or more generated by its auxiliary steam-plant, will enable the company to maintain operations at a satisfactory rate. The Dome Mines will get upward of 1000 hp. and will have to curtail underground operations to some extent. The McIntyre will reinforce a comparatively small supply of power from the power company by about 250 hp. from its auxiliary plant, enabling it to carry on operations at about two-thirds capacity. At the North Crown, which has been allotted 250 hp., the mill has been closed down and underground work on the 500-ft. level will be continued. The Porcupine mine managers will hold a conference with the power-company officials to settle disputes which have arisen as to priority of claims for power and as to the liability of the company for the extra cost entailed by the development of auxiliary steam-power.

The Dome Lake has sold its machinery to the North Davidson. The buildings are being preserved with a view to the possibility of resuming work at some future time.

KIRKLAND LAKE.—Progress is being made with the proposed merger of the Teck-Hughes and Orr gold mines. The plan under consideration includes the organization of a new company capitalized at \$5,000,000 in shares of the par value of \$1, of which 2,500,000 shares will be assigned to the Teck-Hughes stockholders and 1,500,000 shares to those of the Orr, leaving 1,000,000 in the treasury. The King Kirkland has ordered a mining plant and, following its installation, development will be started on a substantial ore-shoot outcropping on the surface.

COBALT.—Power shortage is considerably curtailing production, without any prospect of an improvement in conditions until spring. The Beaver and McKinley-Darragh mines have closed down, but the underground workings of both mines are being kept clear of water, so as to enable operations to be resumed when power is available. The Kerr Lake dividend of 12½c. per share, payable January 15, will bring the total return to shareholders up to \$8,860,000. Production has declined somewhat during the past year, but the discovery of three new veins containing some high-grade ore gives promise of a satisfactory output during the coming season. At the Bailey a two-inch vein of high-grade ore has been discovered at the 240-ft. level which is reported to run 4000 oz. per ton. The annual report of the Coniagas stated that 994,235 oz. of silver had been produced from 97,624 tons. of ore, as compared with 940,267 oz. the previous year. There had been a total distribution of \$10,140,000 to shareholders in dividends and bonuses.

Shipments of high-grade ore were only 5.6 tons, the company being now dependent on the concentration of ores averaging about 10 oz. per ton, the re-grinding of sand tailing, and the cyanidation of slime. A considerable tonnage of low-grade milling rock has been developed.

MEXICO

COPPER AND SILVER MINES SUSPEND OPERATIONS.

MONTERREY.—Unless there is an early improvement in mining conditions in Mexico some of the smelters that are now in operation may have to close soon on account of shortage of ore. From all of the larger mining districts, with the exception of Guanajuato, come reports of the closing-down of mines and the contemplated suspension of work upon other properties. From San Luis Potosi comes the announcement of the closing of the rich mines of the Santa Maria de la Paz Mining Co. which was the largest producer of ore in that State. Rafael Bustamente and associates have ceased to operate their mines in the Velardeña district of the State of Durango. Other mines in that district are also closed. In the Santa Eulalia, Santa Barbara, and Parral districts of the State of Chihuahua the closing of most of the big ore-producing properties has already taken place or is contemplated. Mining operations generally in the rich Pachuca district of the State of Hidalgo have been suspended with the result that the laboring element there is threatening trouble.

The shortage of fuel, together with the low price of silver and copper, is given as the cause of the closing down of numerous mines. It is stated that the Government is seeking to remedy existing conditions. It is expected that coal and coke will be available and equal to all demands within the next few weeks. The strike of coal miners in the State of Coahuila, where the principal fuel supply for the mines of all northern Mexico is obtained, has been settled but the mines were flooded during the prolonged shut-down and it will take some time to drain them and place them on a producing basis again.

AGUA PRIETA.—Details of the recently announced plan of the Mexican government to remove export duty on silver are set forth in the following statement: "When silver is quoted on the New York stock exchange at 60c. or lower, exportation fees into the United States will be revoked. With prices ranging between 60 and 70c., one-half of one per cent duty will be imposed; when between 70 and 80c. the fee will be one per cent; between 80 and 90c. one and one-half per cent. Ores and concentrates will be exported into the United States at an increased rate of one per cent, provided that the market is quoted at the low standard." Silver is now shown at Agua Prieta, for customs-house purposes, at a value of 60c. per pound, and copper at 10c. The prices used in December for customs-house purposes was 80c. for silver and 15c. for copper. During the past year customs-house quotations were as high as \$1.20 for silver and 20c. for copper. The new figures will apply until there are changes in the actual market value of the metals.

UNITED STATES SMELTING COMPANY

In view of the fact that United States Smelting will show a final balance after depreciation, depletion, taxes, and inventory adjustments for 1920 of but \$3.50 per share on the common stock, directors unquestionably were as liberal as could be expected in declaring a 50c. dividend for the final quarter. This makes a total of \$5 paid during the year, the difference coming out of surplus. It goes without saying that last year was the poorest experienced by United States Smelting since 1914, when a balance of but \$1.60 was returned for the junior shares. Last year the earnings were equivalent to over \$14 and in 1916 to over \$20 per share. In the first five months of this year alone net profits were only slightly less than the probable total for the full year. It is understood that all metals were marked down, in determining estimates of the showing for the year, to slightly below present market quotations, which means less than 63c. for silver, less than 4½c. for lead, and less than 13½c. for copper. The drop in silver has been the largest single factor in upsetting the splendid start which the company made in the spring. The price has been more than cut in two. This is of tremendous weight, since production has been climbing and will reach record-breaking figures this year. Purchase of a big lead and zinc property, the Cardonal, and of additional silver mines, both in Mexico, have resulted in some reduction in net quick assets which last year were augmented \$4,000,000 principally as a result of the sale of the interest in the Chrome, New Jersey, refinery. Net quick assets now total about \$12,500,000 or more than the \$12,000,000 note issue. Incidentally, nearly \$1,000,000 of these notes have been acquired by the company in the open market and are in the treasury.

ARIZONA

Miami.—Fire caused almost complete destruction last week of the blacksmith shop, the tool-sharpening room, and adjoining buildings of the Live Oak group of the Inspiration company. It is thought that the fire started from ignition by one of the furnaces of fuel-oil flowing from service-tanks.

Bisbee.—Work of sinking the Junction shaft of the Calumet & Arizona Co. from the 1800 to the 2300-ft. level is progressing satisfactorily; on January 1, 363 ft. had been sunk, and 157 ft. was left to sink. Two compartments are being sunk and the rest of the shaft will be raised. With concreting and the cutting of stations much work will be left when the two compartments have reached the 2300-ft. level. At the Campbell shaft of the Calumet & Arizona Co. there was left on January 1, 427 ft. to strip down to the 1400-ft. level. This will be accomplished in about six weeks, after which it is probable that more sinking will be done.

CALIFORNIA

Death Valley Junction.—The mine and calcining plant of the Pacific Coast Borax Co. have been closed completely, throwing 150 men out of employment. High freight-rates are said to be the cause, as borax from the mines of the company in Asia Minor can be laid down at Atlantic Coast points cheaper than from Death Valley.

Shasta County.—F. A. Zimmerman has sold a half inter-

est in his quartz mine near the old town of Shasta to J. L. Anderson. They announce that they will spend \$10,000 in equipment and betterments and erect a five-stamp mill on the claim in the spring.

The new reduction works of the Shasta Zinc & Copper Co. at the Bully Hill mine will be completed by April 15 according to present calculations. Construction was interrupted for 25 days during the stormy weather in December, but all the buildings are under roof, so that there will be no further delays. The company is employing 220 men. When the plant is in operation it will require about 180 men. The capacity at first will be 300 tons per day. Plans are made to double this later on. The buildings constructed, or under construction, are the reverberatory building, bag-house, crushing section, cooling chamber, bins, and warehouse, the last a building 90 by 200 ft. All buildings are of steel on cement foundations. At one stage of construction steel was bought in the East at \$200 per ton. The same steel is purchased now in the same market for \$130 per ton. Most of the steel used in the construction of the buildings was obtained by tearing down the Balaklala's smelter at Coram.

COLORADO

Leadville.—Production of \$6,535,577 in gold, silver, lead, copper, zinc, manganese, and sulphur is estimated for 1920, the figures being as follows: zinc, 19,754,482 lb., valued at \$1,525,046; silver, 142,285 oz., \$1,233,668; gold, 33,396 oz., \$690,283; lead, 9,328,234 lb., \$419,771; copper, 1,043,034 lb., \$1,525,046; manganese, 5125 tons, \$153,750; sulphur, 8000 tons, \$144,000. A decrease is shown as compared to the 1919 figures of \$2,183,089, or 35.6%.

IDAHO

Coeur d'Alene.—Dividends from the mines of the district for 1920 have been \$5,063,509, compared with \$2,663,500 in 1919. This is chiefly due to the dividends of the Callahan Zinc and the Hercules companies. The latter is not a corporation but a close syndicate which gives no information of disbursement, the figures being estimates. The table of dividends during 1920, and the total, compared with the total of 1919, is as follows:

Company	1920	1919
Bunker Hill	\$1,962,000	\$1,144,500
Caledonia	208,400	312,600
Federal	719,271	450,000
Hecla	650,000	600,000
Hercules	900,000
Callahan Zinc	756,000
Tamarack & Custer	56,400
Lessees	120,000	100,000
Total	\$5,306,271	\$2,663,500

Important reductions on freight-rates on Coeur d'Alene ores have been granted. The reduction in freight-rates on ores to the smelters was vital to the district and the Interstate Commerce Commission finally agreed to it on the urging of the three railroad companies concerned—the O.-W. R. & N., the Northern Pacific, and the Great Northern. The reduction goes into effect on the O.-W. R. & N. and the Great Northern on February 1. These lines handle the ores of the

Hercules and Tamarack & Custer mines, which go to the smelter at Northport. The reduction went into effect on January 1 on the Northern Pacific, which handles ores of the district going to the smelter at East Helena, Montana. The reduced rates are said to be \$3 per ton from the Coeur d'Alene to both Northport and Helena on ores of value not exceeding \$50 per ton, with 25c. per ton added for each additional \$10 per ton of value up to \$4.75 per ton for \$100 ore, and \$5 per ton for ore over \$100 per ton in value.

The following notice has been posted at Kellogg, by the Bunker Hill & Sullivan company:

"Notice to all employees: The price of lead has fallen from 9c. per pound September last to a present price of 4½ and 4¾c. per pound. This is the lowest price in over five years and no longer makes possible the further payment of the present bonus of \$2.25 per shift. The bonus additions, 50c. each, announced July 20, 1919, and February 16, 1920, are withdrawn." The wages paid under the above schedule will be \$4.75 for miners and \$4.50 for muckers.

The general manager, Stanly A. Easton, said that it is planned that local operations will continue at their present full scale and that there will be no curtailment or layoff of men or reduction in the amount of new construction and current building.

NEVADA

Elko County.—The Catlin Shale Products Co., said to be backed financially by the New Jersey Zinc Co., is developing a large deposit of oil-shale in the Elko field. The shaft is reported down 400 ft. in a shale stratum 90 ft. wide. The rock is said to yield approximately 50 gal. of high-grade oil per ton.

Eureka County.—Work by the Ruby Hill Development Co. in the Locan shaft of the Richmond-Eureka mine has been resumed. On the result of operations in the Locan shaft will probably depend the operation of most of the other mines in the Eureka district next spring and summer, as the finding of large and valuable bodies of ore 500 ft. below the present lowest depth of the Ruby Hill mines would encourage deep-level mining elsewhere in the district. During the last three weeks there were shipped from Eureka district, over the Eureka-Nevada railway, to the Utah smelters eight cars of ore from the Eureka-Holly mine; ten cars of ore from the Eureka-Croesus mine, and 72 cars of speiss from the Richmond-Eureka smelters.

BRAZIL

Rio De Janeiro.—The United States Steel Corporation has purchased the large manganese mines situated at Morra Da Mina, about 300 miles from Rio De Janeiro in the State of Minas Geraes. These mines contain large tonnages of good manganese ore and the purchase makes the Corporation independent concerning its supply of manganese ore, which is essential in the manufacture of iron and steel. The company has been receiving shipments from Morra Da Mina for several years. The price is reported as being approximately \$4,000,000.

MANITOBA

Flin Flon.—The Canadian government has made some important modifications of the mining regulations in view of the development of the Flin Flon copper deposit. The rule providing that ores must be treated and refined in Canada has been relaxed so as to permit blister copper to be exported for the final refining process, owing to the cost of sending it to the Trail smelter in British Columbia which is the only place in Canada where the electrolytic refining process is in operation. It is also provided that the product of the Flin Flon mines in which gross recoverable values average less than \$10 per ton shall be exempted from the payment of royalties for a period of ten years from January 1, 1921.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

George Fairbairn has left London for Mexico.

D. D. Moffat was at McGill, Nevada, last week.

Frank T. A. Smith, of Burnet, Texas, is at Los Angeles.

J. B. Davis has returned from Dutch Guiana to San Francisco.

N. C. de Rowne has moved from Berkeley to Socorro, New Mexico.

R. C. Gemmell, accompanied by **C. B. Lakenan**, is in San Francisco.

E. F. Davis has moved from Salt Lake City to Cheyenne, Wyoming.

Charles Billick has returned to Alturas, California, from La Paz, Bolivia.

Edwin T. Hodge has moved from Vancouver, B. C., to Eugene, Oregon.

Walter R. Vidler has returned to Denver from Long Beach, California.

Gordon S. Duncan has joined the firm of Wilkens & Devereux, in London.

R. A. Kent has moved from Leadville, Colorado, to Los Cerrillos, New Mexico.

J. M. Callow is at Superior, Arizona, and expects to return to Salt Lake City next week.

Robert G. Davies, who has been at Guadalupe, Zacatecas, Mexico, is now at Berkeley, California.

Alexander Anderson, of Edinburgh, Scotland, is in San Francisco. He was formerly at El Oro.

Arthur W. Burgren, of Matehuala, San Luis Potosi, Mexico, is at Knight's Ferry, California.

Imer Pett, general manager for the Bingham Mines Co. at Salt Lake City, is in Washington, D. C.

George C. Mackenzie has been appointed secretary of the Canadian Institute of Mining & Metallurgy.

Edmund A. Guggenheim, director of the Chile Copper Co., is now on his way to Chuquicamata to inspect the company's properties.

J. R. Elliott, of Pittsburgh, Pennsylvania, president of the Three Kings Mining Co. at Park City, Utah, is on a holiday in southern California.

F. M. Sylvester, formerly general manager for the Granby Consolidated, is now president of the Moore Group Mining Co., on Alice Arm, B. C.

Mark R. Lamb sailed on January 1 from New York on one of his regular visits to the mines of South America for the New York Steel Exchange, Inc., for which he is purchasing agent.

R. P. McLaughlin has resigned as Oil and Gas Supervisor of California in order to resume practice as petroleum engineer and geologist with an office at 485 California St., San Francisco.

George W. Gray, who for several years has been chief mining engineer for the Dome Mines company, has been placed in full charge of mining operations for the Canadian Associated Goldfields.

George E. Farish has resigned as managing director of the properties in Central America to which he has exclusively devoted his time for the past two years and has resumed his general consulting practice at 25 Broad St., New York.

THE METAL MARKET

METAL PRICES

San Francisco, January 11

Aluminum-dust, cents per pound	65
Antimony, cents per pound	9.50
Copper, electrolytic, cents per pound	14.00—14.50
Lead, pig, cents per pound	5—6
Platinum, pure, per ounce	\$73
Platinum, 10% iridium, per ounce	\$105
Quicksilver, per flask of 75 lb.	\$50
Spelter, cents per pound	8.25
Zinc-dust, cents per pound	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

January 10.—Copper is more active and steady. Lead is livelier and stronger. Zinc is quiet and steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

WORLD'S GOLD RESERVES

Aggregate gold holdings of banks of issue and governments of leading countries increased over \$3,000,000,000 since the year preceding the European war.

In other words, central gold reserves of leading countries increased from \$3,181,000,000 in 1913, to \$6,256,000,000 in 1920, or about 97%. These figures take no account of Russian gold, because no recent figures are available. In 1913, the Russian state bank had \$786,800,000, and in 1917, \$667,041,000. Records for subsequent years are missing.

Government gold counted in this connection is confined to gold held as reserve against currency, and bank figures represent actual vault holdings, exclusive of gold held abroad and of foreign credits.

This growth of gold reserve in central institutions represents in part the result of efforts by the governments to withdraw gold from general circulation and to concentrate it in banks of issue, where it supports fiduciary currency and also is available when international gold payments are to be made.

The following table shows central gold reserves of leading countries at most recent dates in 1920, compared with reserves at end of 1913, divided as to allied countries, Central Powers, and neutral countries, according to a recent compilation of Federal Reserve Board. Figures are millions of dollars.

Country	1920	1913	Change between 1913 and 1920
United States	2098	692	1406
England	738	170	568
France	683	879	4

Eastern Metal Market

New York, January 5.

The new year commences with very little activity in any of the markets. There is a better tone evident in tin and lead but copper and zinc are stagnant and weak. For the two latter metals prices have declined while for the former they have advanced slightly since a week ago. There is considerable optimism as to the future, however, and the opinion is expressed that the worst is over with 1920 and that 1921 will be a satisfactory year.

IRON AND STEEL

The country's pig-iron output fell off sharply last month, the total being 2,703,855 tons or 87,222 tons per day, compared with 2,934,908 tons in November, or 97,830 tons per day. Only 201 furnaces were in blast January 1. In December, 56 blew-out and 5 blew-in, making a net loss of 51. The active capacity at the opening of the new year was 76,540 tons per day, as against 90,040 tons per day for 252 furnaces on December 1.

With the beginning of the year independent producers announce a reduction in standard steel pipe to the Industrial Board basis of March 1919. Another reduction made in the past week was in bar-iron. The new Chicago price at 2.68c. figures back to 2.30c., Pittsburgh, or \$1 per ton below the market for steel bars.

The November exports of iron and steel, totaling 434,297 tons for pig-iron and rolled steel, make the 11 months exports of rolled products alone amount to 357,000 tons per month, or over 15% of the country's 1920 production. As most of the exporting independent steel companies allocated only 10% for foreign shipment, the statistics are an indirect indication of the large volume of the Steel Corporation's business.

COPPER

There has been no improvement in buying. Prices, however, have declined to some extent, but a real test of the market has not been experienced. A sale was made a few days ago of a small lot of electrolytic copper at 12.50c., producer's plant, but it was stipulated that the cash be paid before shipment. Later another sale was put through at 12.75c., delivered, for forward shipment. In the absence of activity the market is generally quoted at 12.75 to 13c., either delivered or New York, depending on the seller, for electrolytic copper for early or fairly prompt delivery. This level will be met by some or all the large producers. Lake copper is nominal at 13.75c., New York.

According to the U. S. Geological Survey the 1920 estimates of production from domestic ores was 1,235,000,000 lb. against 1,286,000,000 lb. in 1919; the output of refined copper, 1,573,000,000 lb. against 1,768,000,000 lb. in 1919; the apparent domestic consumption, 910,000,000 lb. last year as compared with 877,000,000 lb. in 1919 and the stocks of raw and refined copper on December 31, 1920, at 874,000,000,000 as contrasted with 904,000,000,000 lb. at the end of 1919.

TIN

The tone of this market is more optimistic although little business has been done thus far this year. Dealers are showing more interest than for some weeks but consumers have not yet displayed any desire to buy. There were no sales on the New York Metal Exchange the past week but about 200 tons of various lots, comprising metal for shipment from London and future shipment from the East, was sold. For the former \$214 to \$221 per ton was the price with an advance of two to three pounds per ton for the latter position, which was mostly January-February shipment. Spot Straits yesterday was quoted at 36c., New York, which

is about 2½c. higher than a week ago, the tendency having been upward since then. The tone of the whole market is decidedly improved and the feeling is quite general that 1921 will be a good year. London prices yesterday were £200 for spot standard and £210 10s. for future, with spot Straits at £215 10s., all higher than a week ago. Deliveries into consumption in December were 2580 tons with 2856 tons in stocks and landing on December 31. Total imports for 1920 were 50,563 tons against 35,404 tons in 1919.

LEAD

There has been a fair inquiry and considerable business transacted. Most of this has probably been taken by the leading interest at 4.75c., which continues to be its quotation, both New York and St. Louis. Independent sellers are not inclined any longer to meet this price but are asking 5c. or higher in both localities. While those higher levels are not reported to have been realized yet, the market is quoted steady at 4.75c., New York and St. Louis. A better tone in London is a stabilizer here also. In general the market may be characterized as exceedingly firm, but not really strong, and opinion seems confident that the bottom in lead has been reached.

ZINC

The market opens the year with a decline in values and almost stagnation in demand. The only favorable feature is that the London market has advanced rendering less the possibility of further imports in competition with domestic metal in Eastern markets. For this metal about 5.85c., seaboard, is the quotation, duty free, but this is too high to compete with domestic prime Western at central consuming points. Domestic market quotations are easy at 5.50 to 5.60c., St. Louis, and at 6 to 6.10c., New York, but there is a dearth of inquiry. Another favorable phase of the market is the large percentage of retorts out of use.

ANTIMONY

The market is devoid of feature and lifeless at 5.20c. per lb., duty paid, New York, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted by the leading interest at 28.30c. f.o.b. producer's plant, in wholesale lots for early delivery, while the same grade by other sellers is quoted at 22 to 23c., New York.

ORES

Tungsten: Sellers are stiffer in their quotations this week than a week ago and prices are higher, nominally. The belief in, or at least hope for, a tariff may influence this sentiment. Spot ore is held at \$3.25 to \$3.50 per unit. There is no change in the ferro-tungsten market.

Molybdenum: No business or developments are noted and no quotations offered in the absence of demand.

Manganese: Quotations are nominal, there being no demand, at 35 to 40c. per unit, seaboard. Imports continue very heavy, having been 74,477 gross tons in November, bringing the total to 542,189 tons to December 1, 1920, against 296,968 tons to December 1, 1919.

Manganese-Iron Alloys: Ferro-manganese is quoted by British producers at \$110, seaboard, and could probably be bought for less were business offered. Re-sale has sold in one case at \$90. Imports were heavy in November at 7091 tons, so that the total to December 1, 1920, was 53,830 tons or nearly twice the imports to December 1, 1919, of 29,595 tons. Exports were 760 tons that month, which is fairly heavy. Spiegeleisen is inactive at around \$45 or less, furnace.

Book Reviews

The Technical Examination of Crude Petroleum, Petroleum Products, and Natural Gas. By William Allan Hamor and Fred Warde Padgett. 572 pp., ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$6.

This is a manual of instructions for the chemical and physical analysis of petroleum, petroleum products, natural gas, and oil-shale. The book consists of two parts of almost equal length, the first, the book proper, containing theoretical discussion and directions for making the required tests, while a so-called appendix contains mathematical tables, standard specifications, etc. The book will be useful to the petroleum engineer and chemist.

Chemical Analysis of Special Steels, Steel-Making Alloys, Their Ores, and Graphites. By Charles Morris Johnson. Third edition. 541 pp., ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$6.

The author of this book is chief chemist of the Park Works of the Crucible Steel Co. of America. The sub-title shows the book to be particularly devoted to the rapid methods of analysis required in steel-works and other commercial metallurgical practice. The principal change in the third edition is the addition of a number of newly-developed methods of analysis for specific determinations. The book will be useful to the metallurgical chemist.

The Engineering Draughtsman. By E. Rowarth. 237 pp., ill., index. E. P. Dutton & Co., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

As the spelling of the title, as well as the use of the word 'engineering', in place of 'mechanical', indicates, this is an English book, but, nevertheless, well-adapted to the needs of the American reader, particularly the student. It is intended primarily as a textbook for students already familiar with the elementary principles of mechanical drawing. It consists principally of a set of about one hundred exercises, each one comprising one or more line-drawings of a machine-part, the work assigned to the student being to reproduce the drawings with different dimensions, to draw a different view of the part, or in some other way to use his head and show that he really understands what he is doing. This feature makes the treatise an excellent textbook.

Compressed Air Plant. By Robert Peele. 506 pp., ill., index. John Wiley & Sons, Inc. For sale by 'Mining and Scientific Press'. Price, \$4.50.

This is the Fourth Edition of Mr. Robert Peele's admirable and comprehensive treatise on the production and use of compressed air. The new material consists of a chapter on the 'Measurement of Air Consumption', in which data are given respecting the flow of air through orifices and short tubes, and sundry appliances for measuring air both at low and at high pressure are described and explained; and addenda to the chapter on pumping by the direct action of compressed air. This deals with some recent work in air-lift pumping in unwatering deep mines and is of special interest to mining engineers. The author has enjoyed the co-operation of the manufacturers of compressed-air machinery, and in the first part of the book, which deals with the construction and operation of compressors, the theoretical and practical side of the design and use of the machines is thoroughly treated. Most of the second part, the sub-title of which is 'Transmission and Use of Compressed Air', is devoted to problems characteristic of mine-work.

An idea of the scope of this section may be had from the chapter headings: Conveyance of Compressed Air in Pipes; Compressed-Air Engines; Freezing of Moisture Deposited from Compressed Air; Re-heating Compressed Air; Compressed-Air Rock-Drills; Hammer Drills; Coal-Cutting Machines; Channeling Machines; Operation of Mine-Pumps by Compressed Air; Pumping by Direct Action of Compressed Air; Compressed-Air Haulage in Mines; and Measurement of Air Consumption. The author will be recognized at once as the editor-in-chief of the only complete handbook for the mining engineer—'Peele'. This is sufficient to assure the high standard of the treatise on compressed air.

Hand-Book of Mexican Properties and Securities, 1920-'21. Compiled by J. S. Curtiss & Co., El Paso, Texas. 390 pp., index. For sale by 'Mining and Scientific Press'. Price, \$5.

This book is the result of ten years labor in the collection of data, primarily on the general subject of securities, relating to the Republic of Mexico. It lists alphabetically the names of all the Mexican States, banks, Government bond issues, national railroads, cotton plantations, oil companies and refineries, mines and mining companies, ranches and ranch-owners. In addition, it carries other valuable matter such as a translation of Mexican mining terms, list of Government mining agents in each State, copy of the mining laws and their regulation, and a list of public utilities and industrial stocks. In view of the present bright prospects for a restoration of law, order, and security to investors in Mexico, this book has an interest which will be accentuated as time goes on. It will be valuable to anyone interested either as an investor or merchant, who has in contemplation opening up business relations in the territory south of the Rio Grande.

Cost of Mining. By J. R. Finlay. 532 pp., ill., index. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$6.

Ten years ago Mr. Finlay's 'Cost of Mining' was received with enthusiasm by the members of the profession as being the most comprehensive as well as the most reliable (the difficulties in obtaining entirely reliable data are only too well known to most of us) compilation of information on the elements of cost in mining coal, iron, copper, and the other more important metals. His book, however, was more than a compilation, for Mr. Finlay had clothed the bare figures with his comment and analysis; his twenty years of varied experience had given him an unusual insight into the economic problems involved in mining different metals in different regions. In the present volume the reader familiar with the earlier edition will find it enriched by ten years of riper experience on the part of the author. Mr. Finlay, unnecessarily, we think, asks indulgence for interjecting material of a broader scope and some "generalizations on geologic history and processes" among the statistical matter. Indeed, the question was entertained of changing the name of the book; this was decided in the negative in spite of the fact that the name hardly does justice to the new edition. The winning of metals as an economic problem intricately connected with other industries is considered from sundry angles; the valuing of mines, the financing of them, and the marketing of their products are discussed from a broad standpoint. As the author says, mining is an industry with which 20,000,000 English-speaking people are directly concerned and in which a great many more are vitally interested. It commands the interest of perhaps 20% of the people in the world. 'Cost of Mining' is an unusual book that may well be read with benefit by every thoughtful student of world conditions today; it is one that no mining engineer can afford to be without.

A. B. P.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

HOW TO JOIN BELTS

By F. D. Rich*

Human nature plays an important part in getting service and longer life out of a belt. It is human nature to do things in what seems the easiest way, not always realizing it is often the most expensive and usually the most laborious, because it necessitates doing the work over and over again. This applies particularly in the case of cutting belting and joining it.

Cutting the ends of a belt to put it into service seems such a simple thing that often the belt-man does not give it the consideration necessary to ensure the best results, and much of the difficulty with otherwise good belts is due to their not being cut and joined accurately.

When a belt runs wobbly or races back and forth across

which prevents smooth running. Even the use of a straight-edge does not assure the perfect results obtained by using a square, for the slip of a fraction of an inch will bring the belt ends together at an angle, as shown in Fig. 1.

This results in the belt 'shimmying' on the pulleys, which is bad for the belt and impairs its service, imposing shifting and irregular strains, which no belt can stand indefinitely.

There is only one way to assure correct results. That is to use a belt-square and to keep it in place until you have cut all the way through the belt. Don't just scratch the surface and then hack through. Cutting to the square assures an even cut all the way through the belt and all the way across. It means that the belt ends can be brought together in a tight, even-running, flush joint.

Be sure your knife is sharp. Wet the point of your knife occasionally, as it cuts more easily when the blade is wet.

When a number of belts have to be cut, a good stunt is to drive two nails in a large block of wood, and against these set the edge of the belt and the edge of the square, as shown in Fig. 2. This prevents either the belt or the square slipping. Some men tack a slip of leather or a piece of old belt on the end of the block to protect the point of the knife as it comes through the belt.

Wide belts are more difficult to square correctly, and the difficulty is often increased by slight variations in width, which throws the square out. To avoid this and assure perfect results, the method described below has proved the best.

At any point near where you are going to cut the belt, measure across and find the centre, as at 'A-A', Fig. 3. At any distance back of this, 2 or 3 ft., find the centre again, as at 'B-B'. Between these two centre points draw a clean sharp line. This marks the centre axis of the belt.

Now, as in Fig. 4, using the square against the centre line, trim off the end of the belt, holding the square firmly in position while you cut all the way through. Two small nails driven in on the centre line will keep the square from slipping.

For cutting the other end of the belt, find the centre line, the same as just described. Then at any point on this line other than where your belt clamps will come, take a point 'C' as in Fig. 4. Then using the square as illustrated, draw a line 'D-C-E' at right angles to the axis, and all the way across from edge to edge. This line 'D-C-E' will constitute a 'base line' to measure from after the belt is in the clamps. Do not cut on this line.

You can determine exactly where you want to cut after the clamps have been put on and the belt brought into position. Then measure forward from the line 'D-E' an equal distance on each side of the belt to the cutting-point. You can use calipers and measure over the belt-clamp or run your ruler through the edges of the clamp. As a matter of convenience, always cut one end of the belt square and get it ready for making the joint before putting the belt into the clamp.

Personally, the writer, who has had considerable experience in working with belting manufacturers in solving the difficult problems of efficient belt joining, is very much opposed to methods which punch holes in the belt or which in

the pulleys, it is not giving its best service nor can it have its longest life. If you have a belt that is repeatedly jumping off the pulleys, you are paying about twice as much as you should for it, because its life is being shortened and you are paying for power that is lost and production that you don't get. You are also repeatedly paying for unnecessary time and labor in fixing things up.

Provided that its ends are cut square and it is joined with care, a belt can be made to run as straight as an arrow if the pulleys are lined-up true.

Don't guess at cutting your belt-ends. Use a square—always—and use it with care. If you do not use a square, one or both of the ends will be cut unevenly or irregularly,

*Mr. Rich is sales manager for the Crescent Belt Fastener Company.

any way cut or weaken the lengthwise power-carrying fibres of the belt.

It is no uncommon thing to see, in journeys through manufacturing plants, laced belts in which from 40% to frequently more than 70% of the cross-section of the belt is removed in punched holes. How in the name of common sense can such a belt-joint (see Fig. 5) be expected to give the full service of the belt? Many manufacturers are today running belts much heavier and more expensive than their requirements, in an attempt to get strength at the joint.

Below is a table showing the qualifications of the perfect belt-joint, by which any engineer can check up the comparative efficiency of his own methods.

(1) Will maintain maximum strength of belt.

(10) Is safe against accidents or breakdowns.

(11) Must be easily and quickly made without special equipment.

(12) Will last for the life of the belt.

But regardless of what method of joining is used, the belt should always be cut square, so that it may exert a straight-line pull and perform its function of power-transmission efficiently.

OIL-MEN WITNESS REMARKABLE WELDING TESTS

The recent Gas show at Buffalo brought together men in all branches of the industry from every part of the country. In the course of informal discussion on oxy-acetylene welding of oil pipe-lines a big Kansan questioned the strength of

Welded Pipe. Break in Threads.

Welded Pipe. Break in Standard Cap.

(2) Will avoid destruction or weakening of the lengthwise power-carrying belt fibres.

(3) Should prevent breaking the belt back of the joint.

(4) Must not hammer on the pulleys.

(5) Must not be subject to wear or to crystallization.

(6) Will ensure continuous uninterrupted operation without supervision.

(7) Hugs the pulleys tightly and ensures full transmission of power.

(8) Runs silently, same as endless.

(9) Can be easily taken apart for removing or shortening the belt.

the welded line to hold up under the service pressures in his field. Of course there are abundant instances where welded lines are in service in oil districts, carrying pressures of 800 to 900 lb.; but the skeptic was not entirely satisfied. What he wanted was a breaking-pressure test to determine just where the welded pipe would give way under breaking-strains. In his opinion the break would occur in the weld.

The discussion took place, as it happened, in a stronghold of oxy-acetylene welding. One of the factories and machine shops of the Linde Air Products Co. is situated in Buffalo, and it is in its big Buffalo laboratory that the development department engineers of the company conducted its experi-

ments and tests in working out application problems for users of oxygen and acetylene in welding and cutting. This circumstance led to a series of tests to finally settle the matter in the minds of those concerned.

A test was made with 4-in. pipe. Two short lengths were welded together, the ends threaded and two extra-heavy standard caps screwed on. In this test one of the cap-heads blew out at 4400 lb., which gave a total end-pressure on the cap of approximately 33 tons, proving that the broken cap was not in any respect defective. The weld was not impaired at all. After this test it was suggested that an entirely new weld with other pipe lengths of the same diameter be tried. Accordingly, two more lengths of 4-in. pipe were welded, threaded, and sealed, this time with extra heavy steel caps made to withstand a working pressure of 3000 lb. of air. The pressure was applied and the pipe gave way in the threads at 4200 lb. In all of the tests the welds held securely.

The gentleman from Kansas decided that if there is anything stronger than a good oxy-acetylene weld it is not needed in the oil-fields of the South-West. He examined a large number of welded-pipe specimens that had been subjected to hydrostatic breaking-tests, finding that in no instance had the pipe given way at a weld. He also inspected the shop welding and testing-equipment with unusual interest, from the familiar Oxweld blow-pipes to the big pumps that supply pressure for tests up to 10,000 lb. per square inch.

STOCK-SUBSCRIPTION PLAN FOR DU PONT EMPLOYEES

E. I. du Pont de Nemours & Co. has announced a new plan for stock subscription by employees. The board of directors of the company has modified the former plan for stock subscription, which has been in effect since 1909, and has made important changes for the purpose of providing an opportunity for employees to invest their surplus earnings in such a way as to share in the profits of the company while enjoying the security afforded by the debenture stock. Employees who become stockholders under this plan will receive not only a fixed cumulative dividend on their stock, when declared, but also a participating payment at a rate increasing with the net earnings of the company and also a service payment based upon the length of service credited to them.

The plan for the participating payments based on the net earnings of the company provides that if the net earnings were at a rate equal to or greater than 8% but less than 9% per annum on the combined total invested capital, the participating payments will be at a rate of \$1 per share per annum.

The payments increase as the earnings increase until, if the net earnings were at a rate equal to or greater than 12%, the participating payments will be at the rate of \$5 per share per annum. The rate of service payments will be based on the years of continuous service with the company and will be made on the following basis: for length of service of one year and less than two years, \$1 per share per annum; for a service of two years and less than four years, \$2 per share per annum; for a length of service of four years and less than seven years, \$3 per share per annum; and for a length of service of seven years or over, \$4 per share per annum.

Under this plan, therefore, if a participant has been in the service of the company for seven years or more, and if the company's net earnings for the preceding year were at a rate of 12% or more on its combined total invested capital, subject to the declaration and payment of the regular cumulative 6% dividend, such employee will receive in all 15% or \$15 for the following year on each share of this debenture stock.

Any eligible employee may subscribe to an amount of this stock equivalent to not more than four times his monthly rate of salary or wages, but in no case to more than 20 shares. The plan provides that the stock must be paid for within one year. Those who desire to have their stock redeemed can do so under certain conditions. The stock will be redeemed by the company at \$100 per share.

COMMERCIAL PARAGRAPHS

The Mine & Smelter Supply Co. announces the appointment of J. L. Harman as manager of its branch house at El Paso, Texas.

Catalogue 'F', issued by the Ross Heater & Manufacturing Co., illustrates and describes the various types of heaters, condensers, expansion-joints, coolers, and 'Airjector-pumps' manufactured at the company's plant in Buffalo, New York.

The Victory Engineering & Sales Co., Monadnock Bldg., San Francisco, has issued an attractive catalogue in which are listed a complete line of pipe-fittings, pump equipment, and pumps. The Victory oil-motor is a feature of the company's products.

Bulletin No. 14-C, recently issued by the National Tube Co., of Pittsburgh, discusses tubular steel poles, and outlines various uses in industrial plants, railroads, municipal construction, and elsewhere. Some valuable data are given regarding the properties and specifications of pipe.

The business heretofore carried on at Waldo, New Mexico, by Grubnau, Bryant & Grubnau, as manufacturers of oxide of zinc, has been acquired with all assets and liabilities by the Grubnau Chemical Co., incorporated under the laws of the State of New Mexico, and will be continued by this company in the same way as heretofore.

James R. Mougins, sales engineer for the Mine & Smelter Supply Co., has been transferred from New York to Chicago. His address is 4555 Malden St. Mr. Mougins will look after the sales for the company in the Central States territory, and all inquiries originating in this territory for Marcy ball-mills, Marcy roller-mills, Wilfley tables, and the company's other specialties will be taken care of by Mr. Mougins.

The Chicago Pneumatic Tool Co. announces the resignation of H. L. Dean, formerly manager of the Division of Compressor and Engine Sales. The company also announces the appointment of J. F. Huvane as Eastern manager of Compressor and Engine Sales, with headquarters at 6 East 44th street, New York, and G. C. VandenBoom as Western manager of Compressor and Engine Sales, with headquarters at 300 North Michigan Blvd., Chicago.

The Oxweld Acetylene Co. announces the appointment of the Standard Supply & Equipment Co., of New York and Philadelphia, as Eastern sales agent for 'Eveready' welding and cutting-apparatus and supplies. The Standard Supply & Equipment Co. deals in shelf and heavy hardware, machinery, mill and mine supplies, automobile accessories, etc., and has, besides its New York and Philadelphia establishments, branch houses at New Haven, Hartford, Springfield, Worcester, Pittsburgh, Trenton, and Altoona.

C. E. Grunsky Company, consulting engineers and economists, call the attention of their clients to the fact that they are prepared to assist them in their economic business problems requiring technical analysis. These problems include valuation and business analysis as a basis for determining the proper depletion and depreciation factors for use in preparing income-tax returns and in making adjustments with the Internal Revenue Bureau. The establishment of proper methods of obtaining the present worth of all business having wasting assets, and the preparation of appraisals of plants and equipment for incorporation and other purposes are undertaken. The company's office is at 57 Post street, San Francisco.

MARCY ROLLER MILL

THE Marcy Roller Mill represents a high development in grinding machinery and in this respect is in the class with the Marcy Ball Mill.

The open end feature, through which the conditions within the mill may be observed while running, brings about low cost of operation.

Rods or rollers can be used in a tube mill but for the best results, *bent and broken rods must be removed.*

High efficiency in the roller mill is obtained by the low pulp line as in the Marcy Ball Mill.

Thirty six large size Marcy Roller Mills are now being manufactured for one of the large mining corporations of the Southwest.

We will be glad to advise on your crushing problems

EVIDENTLY there will be more Cabinet disappointments than appointments and quite as evidently the final choice will indicate whether Mr. Harding's administration is to be reactionary or progressive. Upon his choice will depend not only this cabinet but the one to be selected four years hence. It has been well said that the title of Secretary of the Interior would seem highly appropriate to our late Food Administrator; so would Secretary of the Department of Public Works; but we have not departed from our notion that it would be a pity to spoil Mr. Hoover's career by putting him into a cabinet in which he is sure to be uncomfortable, and therefore probably ineffective.

AS an example of the waste of public money, we mention a 100-page pamphlet received under the frank of Senator W. L. Jones giving the testimony of our friend Mr. William Denman before the committee of the House on Shipping Board operations. This gives Mr. Denman's personal views, including "an appreciation of General Goethals", with whom he had a regrettable public disagreement when he himself was chairman of the Shipping Board. We do not say that Mr. Denman's views on these or other matters are not interesting, but we do say they are not of such interest or importance as to warrant the spending of public money in paper, printing, and postage.

THE silver production of the United States last year is estimated at 56,564,504 ounces, out of the world's total output of 165,000,000 ounces. Thus our production of silver in 1920 was almost exactly equal to that of 1919, the difference of 17,941 ounces being within the limits of statistical error. Likewise the world's production of silver decreased only slightly, the difference being estimated at ten million ounces. This shows how much the steadiness of the supply contrasted with the vagaries of demand, for the price of silver ranged between \$1.38½ and 59½ cents during the past year. The world's consumption of silver in 1920 for coinage alone is estimated at 225 million ounces, which compares with 200 millions in 1919 and 238 millions in 1918. To these totals may be added about 125 million ounces annually for industrial purposes. Evidently the production is considerably less than the consumption, but the re-melting of large quantities of silver in various forms and from diverse sources renders

it impossible to make a direct and trustworthy comparison. On the whole, however, the evidence of trade statistics favors an optimistic view of the probable future course of market quotations.

CREDIT is due, and will have been given gladly, to President-elect Harding for his good sense in requesting an abandonment of the plans for a costly celebration of his inauguration to the Chief Office in March. He sent a letter-telegram on the subject to the chairman of the Washington Inaugural Committee and it was couched in terms of simplicity and sincerity that must have made an effective appeal to all thoughtful citizens. The decision to make the ceremony "a wholesome example of economy and thrift" is well advised, but we fear that it may deceive the country into the belief that our national legislature is committed to the policy of stopping the waste of public money.

NOMINATIONS for officers of the Institute have been made and the ballots issued to members. As only one ticket is in the field, it will be elected, of course. We note with pleasure that the next president will be Mr. Edwin Ludlow, now first vice-president. Mr. Ludlow has been identified chiefly with coal mining, in this country and in Mexico, but he is a man of wide engineering experience and possesses an ample understanding of the metal-mining industry. He has been a keen supporter of the Institute and a regular attendant at its meetings for a long period, so that he is personally known, and liked, by a larger proportion of members than most of his predecessors. He has executive ability, keen intelligence, and an engaging personality; therefore he ought to prove an excellent president. We wish him every success in his year of office.

WE take pleasure in publishing an article on the famous deposits of pyrite in the Huelva district of Spain, commonly identified with the mining operations of the Rio Tinto company. This article is contributed by Mr. Courtenay De Kalb, formerly Associate Editor of the 'Mining and Scientific Press'. Mr. De Kalb was engaged two years ago by the U. S. Department of Commerce to make an investigation and report on the mining and metallurgical industries of Spain. This account of the Huelva deposits represents a part of the large mass of valuable data collected by him while in Europe. To

his article we append a timely and interesting summary of the history of the ancient mines of the Huelva district by Mr. D. W. Brunton, who was engaged several years ago by the Rio Tinto company to advise upon the best method of mining applicable to local conditions. We shall publish an interview with Mr. Brunton at an early date.

HERE are 20 stockholders of record of the Broken Hills Silver Corporation selected on January 7, almost at random from a list of 1000 or more." This is quoted verbatim from a two-column advertisement that appeared recently in a San Francisco newspaper. There follows a pretentious list of bankers, office-holders, and others, headed by Mr. T. T. Ansberry, "Attorney for Governor J. M. Cox of Ohio" and Mr. Ed. Malley, State Treasurer for Nevada. That the ad-writer overlooked the fact that Mr. Cox became ex-Governor on January 1, indicates lack of discrimination, but that oversight is more than amended by the meticulous regard for the exact truth exhibited by qualifying "at random" with "almost". If 'almost' had been omitted the immutable laws of probability would have proved that no one of the fortunate thousand held a position less distinguished than that of director of a bank or warden of a State prison. But 'almost' leaves a substantial loop-hole; there may even be some stockbrokers and bootleggers among the 980 who are not classified. Evidently "almost at random" leaves much to the imagination in describing a method of selection; it is about as definite as the reply of the negro miner in Georgia who when asked how much ore remained in the bin replied, "Well there's right smart and yet not so very much either."

THE other day we were talking to the superintendent of a large and well-known concentrator in which flotation plays a part in the scheme of treatment; his views on the question of publicity with regard to the operations of his company are particularly interesting because of the contrast with the attitude taken by a great many users of flotation who are not licensees of Minerals Separation. We, of course, respect this attitude of reasonable reticence because we may not be aware of all the facts in a particular case. Our friend the superintendent said in substance, "I am confident that there is a man working in our mill today who, unknown to us, is keeping Minerals Separation apprized of everything done in our flotation department. Any good practical millman can get an accurate idea of what is being done without actually seeing the complete metallurgical reports. Moreover, if a suit is started, Minerals Separation simply goes into court and gets an order compelling us to produce our records. A moving-van comes around to our office and they take every scrap of paper in the place to court, where they introduce whatever they want as evidence against us. For that reason I personally see no object in suppressing the publication of articles giving every detail of operation. There is even an advantage in that some other operator who prefers not to saddle himself with one of Minerals Separation's 'generous' con-

tracts may find something helpful. We condemn Minerals Separation for withholding data regarding new developments and it seems to me inconsistent that we should do the same thing ourselves". Some of those who favor a policy of secrecy feel that if Minerals Separation learns of anything new or novel it will immediately take out a new patent and thereby add another tentacle to the sixty or seventy it already possesses. In this connection attention may well be called to a fact that is generally overlooked by those who have inventions, namely, that the publication, especially in a reputable technical periodical, of the details of a new device or process before it is patented is one of the most effective ways of protecting the idea. Such publication definitely fixes a date prior to which the invention was developed, and if the journal is one of general circulation among the members of a particular profession it furnishes strong presumptive evidence that a subsequent inventor derived his inspiration from reading the published description. A concrete example is the litigation over the process of vacuum-leaf filtration, wherein the publication, on our suggestion, by Mr. George Moore of an article describing his theory of filtration, through a porous leaf, of the liquid portion of a metallurgical slime, leaving the solid in the form of a cake on the surface, played an important part in establishing the priority of his invention, as against Mr. Charles Butters. As we said before, we respect the wishes of those who do not desire to give publicity to their operations, and under some circumstances we can recognize a valid reason for their attitude, but, it is rarely justifiable, or even advantageous to them, and is always a drawback to the progress of the metallurgical art.

A Noble Benefaction

In our last issue we devoted one of our advertising pages—number 32—to an appeal from the European Relief Council in behalf of the starving children of Europe. Mr. Franklin K. Lane, formerly Secretary of the Interior, is treasurer of this fund, which is being administered by Mr. Herbert C. Hoover. The devastation of war has left the populations of the belligerent countries of Central and Eastern Europe in a condition of pitiable destitution. For some of this they are themselves responsible, but the 3,500,000 of innocent and helpless children, exposed to famine and misery, make an appeal that must overcome any of the ill feeling surviving from the days of war. The appeal is not for all the children but only for the 3,500,000 that are reported, on competent American authority, to be in immediate danger of death by starvation. Ten dollars will provide for one child during this winter. The sum of thirty-three million dollars is asked. Mr. Hoover says that there are in Europe today from twelve to fourteen million children between the ages of three and sixteen that are "bereft of parents, home, comfort, and the opportunities which should be their heritage". For every American dollar that is contributed the governments and the citizens of the afflicted regions will give two dollars in transportation and service. We can trust Mr. Hoover to make this

help practical and businesslike; he never wastes money and never asks for financial assistance without insisting upon supplementary contributions and co-operation from those most immediately related to the beneficiaries of his scientific charity. Of course, the amount of money asked for this noble purpose is small indeed if compared with the vast sums squandered by our people on luxurious living, for example, in candy, Christmas presents, and private automobiles. It will be raised without a doubt, and while it is being collected we may remind ourselves again of a part of our own responsibility for the unhappiness it will alleviate, since the failure of our Government to make peace with the governments of the countries with which we have been at war is one of the causes of the deplorable condition of continental Europe, especially the Central and Eastern regions. The poverty of the old world is the direct result of war and the preparation for war. Our own vast governmental expenditure is due mainly to the same causes; indeed, two-thirds of the money voted annually by Congress is absorbed in military and naval expenditures even during normal times. We hope Mr. Harding will carry out his promise to take the lead, in behalf of the United States, in a new effort to induce the disarmament of the nations and the creation of an association for preserving peace, and thereby save the world from untold pain and trouble.

The Flotation Litigation

In this issue we publish a comprehensive account of the present status of the litigation arising from the use and alleged infringement of various flotation patents in this country. The reading of this summary of the decisions and procedures of the courts will impress the members of our profession with the inadequacy of the tribunals before which such highly technical disputes have to be tried; they will note the discrepant nature of the juridical logic, the contradictory character of the opinions, and the fortuitous conclusions that seem to mark an appeal to the law. No man can foretell what the outcome of a suit may be, however well informed he may be concerning the facts and the arguments; the psychology of the human element in the judges is beyond the shrewdest guess; it is a gamble! Most wise men know this and keep out of the courts. So far the patent-exploiting corporation, Minerals Separation Ltd., with its American subsidiary, has had the best of it; but the defendants are not dismayed; on the contrary, as we are informed, they feel cheerful over the probable outcome of the concluding stages of the litigation. In our rôle of observer we venture to say that the defendants are better served in the matter of legal talent than heretofore, when they have suffered from mistakes that it did not require a lawyer to detect. However, the eventual result of all this legal wrangling is one that no man can predict, it is in the lap of the gods, that is, it is dependent upon the digestion of sundry fallible mortals. Meanwhile a suggestion for a compromise and a settlement has been made; we made it ourselves at the Flotation Con-

ference of the American Mining Congress. Since then the president of the Congress, Mr. W. J. Loring, has acted upon the offer, made by Mr. Alfred A. Cook, counsel for Minerals Separation, to meet with a committee of the Mining Congress, with a view to discussing the remedies possible for meeting the difficulties and ameliorating the irritating conditions created by the methods, practices, and license agreements of Minerals Separation in their impact upon the mining industry. Mr. Loring has appointed Messrs. Bulkeley Wells, J. Parke Channing, Gilbert H. Montague, with himself, *ex officio*, as the committee for this purpose. Mr. Wells was president of the Congress last year, he is the head of a number of important mining enterprises, in Colorado, California, and Nevada; Mr. Channing is vice-president of the Miami Copper Company and is identified with the mining operations of Adolph Lewisohn & Sons; Mr. Montague is a distinguished lawyer of New York and counsel for the Mining Congress in its complaint against Minerals Separation before the Federal Trade Commission; Mr. Loring himself is a mining engineer of international reputation and is the manager of important mines in Nevada and California. The committee, therefore, is representative and capable. In order that there may be no misapprehension as to the purpose and scope of the inquiry to be made, we quote from the final telegram sent by Mr. Loring to Mr. Cook, as follows: "American Mining Congress Committee does not ask Minerals Separation to admit correctness of charges or criticisms before Federal Trade Commission. Committee does not desire to discuss with Minerals Separation these or any other charges or criticisms. Committee most earnestly desires to discuss constructively with Minerals Separation any specific measures for relieving present situation. You offered at Denver to take up with us the various problems we think are oppressive to the mining industry. This is the exact purpose for which the Committee understands the conference is to be held." Mr. Cook replied that he and his associates would be "most happy" to meet with the Committee on the basis of this telegram. We hope that the outcome will inure to the benefit of the mining industry. It is not within the scope of this committee, so far as we can infer, to attempt to bring about a settlement of the main issue; indeed, it may be beyond the power or goodwill of anybody to do so, but evidently it would be greatly to the benefit of the mining industry if this miasma of inquisition, interference, and litigation could be lifted. As to that, any such consummation will be in the nature of a compromise, that is, on the one side, the Minerals Separation people will have to forego their claims for punitive damages from the alleged infringers of their patents, and, on the other side, those who have used flotation processes claimed to be patented by Minerals Separation will have to pay something rather than leave the ultimate decision to the courts. Whatever the outcome of the litigation, it is going to cost at least \$250,000 per annum for each side, and the final result is uncertain. The alleged infringers may escape some of the penalties imposed by the courts, but not all; they may be mulcted

for millions of dollars. The Minerals Separation people have been trying for nine years to squeeze money out of the recalcitrant users of their patents and have failed to bring them to their knees; the principal proprietors have seen their expected profit put out of their reach again and again, and meanwhile they must be aware of the fact that so long as the basic principles of flotation remain a matter of conjecture among physicists and chemists, so long will they be exposed to the danger of a discovery, to be converted into a patent, that may set aside and override all the advantages they now hold. These are far-reaching considerations, and we doubt whether the committee appointed by the Mining Congress will care to go into them. However, we cherish the hope that these and other matters pertinent to the controversy will be duly considered and that the meeting of representatives from the opposing camps will lead to a better understanding all round, preparing the way for an armistice, and possibly for a peace, with reparations.

The Institute as a Publisher

The affairs of the American Institute of Mining and Metallurgical Engineers are the affairs of the American mining profession, so we need hardly apologize for discussing them. We are prompted to do so by several protests received by us against the recent "voluntary subscription", which is set down as one of three items on a bill for dues. We publish one of the letters received by us; it is from a distinguished member of the Institute. This year, instead of a simple bill for the dues, namely \$15, each member is debited with \$2 for binding, whether he wishes volumes LXV and LXVI bound or not, and at the same time he is told that even volume LXIV has not been issued and cannot be issued until next year. The date of the circular is December 17. Next, he is put down for a "voluntary subscription" of \$10, making \$27 altogether. At last week's meeting of the San Francisco section of the Institute this subject was debated. We were not present, but it is reported that a resolution was passed unanimously, by 50 or more, calling for the appointment of a committee to investigate the expenses of the Institute and devise plans for reducing them within the limits of income. Captain J. C. Ray, who said that he had been absent from all the meetings for three years and had only just returned from military service abroad, made the remark that there was much talk about the desirability of having engineers in the Government administration because their training would enable them to introduce economy and efficiency; yet the first thing he heard on his return was this request for a contribution of \$10 to make good a deficit caused by the failure of the engineers to run a business that was entirely under their control. This seems to us a just remark, even if unpalatable to most of us, but in the long run it is wise to face unpleasant facts honestly. In a recent circular the Finance Committee explains that the funds of the Institute have been exhausted by its enlarged activities and the great increase in the cost of publishing, printing, supplies, and salaries. A tentative budget for 1921 in-

dicates a deficit of about \$20,000. The directors believe that the present high costs are temporary and they feel that the activities of the Institute should not be curtailed. This is not a cheerful story, nor is it by any means unique, for many other organizations are feeling the effect of high prices and possibly the results of their own extravagance during an expansive period. It has seemed to us often during recent years that the Institute has become too exuberant in its publishing activities. Its Transactions have been voluminous to excess; they exhibit a lack of revision; if properly edited their bulk could be decreased 30% without loss to their value as technical literature; when received a considerable proportion of them goes into our waste-paper basket almost of their own accord. It seems to us that the Institute has been publishing a good deal of half-baked material, swelling the Transactions into two and even three volumes per annum, instead of the one compact well-edited book we used to receive when Dr. Raymond was editor and secretary. Not content with expansion in this direction, the Institute has seen fit to publish a monthly magazine, partly to serve as an official organ and partly to extend its commercial activities. Here it is proper to interject that the Institute magazine is in no sense the competitor of any technical journal, such as the 'Mining and Scientific Press' or the 'Engineering and Mining Journal', and any criticism of it is without prejudice. For example, the January number of the Magazine is just to hand, and we confess with regret that we can find nothing in it that is worth the price of paper, printing, and postage. The chief feature of the issue is an article on economic conditions by Mr. W. R. Ingalls. This is good, but most of us have already read Mr. Ingalls' views on the subject in 'The Annalist', the 'Mining and Scientific Press', and other periodicals. The account of the Engineering Council dinner is interesting to those who participated, but to few besides. This applies also to the chronicle of society activities, namely, those of local engineering organizations. Five pages are given to abstracts of papers to be presented; not one of these is of any such immediate importance or general interest as to justify its being printed more than once, in pamphlet form for the meeting, and later in a bound volume. Six pages are devoted to abstracts of important papers in current periodicals. These also fail to justify the publication of a 100-page magazine. Then comes a list of new members and of additions to the Engineering Societies Library, with other odds and ends. The Magazine is not worth the price it costs; everything in it that is essential could be sent to members in an 8-page folder; it seems to serve as an editorial kindergarten for a number of young men in the Secretary's office, thereby diverting energies that are badly needed for the Transactions. If the Institute is to remain solvent it had better curb its use of paper, printing, and postage, that is, cut down its effusiveness as a publisher. It is time for the directors to face facts and consider seriously what are, and what are not, the functions of a professional society such as the Institute. As to that there will be various opinions. We venture to express one of them.

DISCUSSION

Ex-Soldiers and Prospecting

The Editor:

Sir—In your issue of December 11, 1920, I notice a short editorial which commends Government assistance to returned soldiers in order to enable them to go prospecting for minerals. Such a scheme, which you say the Government of Western Australia reports as being successful there, is in operation also in British Columbia, but all reports of its success would be more complete and interesting if they stated for whom the prospecting was "successful".

Those schemes, which have been quite widely boosted of late in nearly every mineral country in the northern half of America may be highly "successful" from the point of view of some mining engineers and the companies they represent, because they are interested in keeping the market continually flooded with vast numbers of mineral prospects, so that a few of the best of them can be picked out and purchased for little, or nothing if possible, but they do not look quite so "successful" to the professional prospector who has spent the best years of his life and every dollar he could earn in the meantime in the hills looking for and developing prospective mines, nor will they appear very "successful" to the returned soldier prospector by the time he has acquired a tithe of the experience of the old professional prospector, who is usually altogether too inarticulate for his own good.

Some of the reasons why prospecting for most minerals is likely to be very unsuccessful to the man who actually does the prospecting are as follows:

Because there is no demand at present for any of the metals, excepting gold, and even that, unless the prospector is lucky enough to find it as a shallow alluvial deposit or as an absolutely free-milling quartz deposit, so that he can make it productive by his own efforts, will not do him much good, for the simple reason that otherwise he will be left with a white elephant on his hands, like the thousands of other claim-owners, many of whom have good likely-looking propositions near existing lines of transportation, which they are unable to work for themselves from lack of modern machinery or the means to buy it, and therefore must hold indefinitely or sell at their (the companies') figure to the mining companies that have the necessary capital and know it and take advantage accordingly, for every experienced mining man knows that hardly ever does a prospector who is fortunate enough to find a really good prospect, which soon develops into a mine, get enough for it to adequately

repay him, for the risks he has taken, the time and money he has spent, the disappointments he has endured, and the sacrifices he has made in order to find it.

As I pointed out to the British Columbia government over a year ago, if their intention was to benefit the returned soldier and incidentally mining, it would be much more sensible to develop a few of the best of our many thousands of already discovered but undeveloped prospects, many of which belong to returned soldiers, than to spend public money and the time of young soldiers looking for more mineral claims, raw and undeveloped, of which we have far too many already; and I feel confident that true conditions are much alike in all the mining regions.

The fact is that no government or individual can conscientiously recommend young soldiers or anyone else to prospect for minerals under present conditions, excepting, of course, 'hoochite', which you so humorously described a few numbers back, as hoochite solution always is in demand at high figures wherever humans congregate.

DONALD C. SIMPSON.

Smithers, B. C., January 5.

The North Star Mines

The Editor:

Sir—In the interview about the North Star mine and mill of Grass Valley, California, in your issue of December 25, 1920, you omitted, no doubt through oversight, to mention any of the details of John Hays Hammond's connection with the property in the early days, and to whose efforts was due the resuscitation of the famous mine and making of the property a producer of promise, before James D. Hague and Arthur De Wint Foote became connected with the company. During that period, and when the mill was being constructed, I happened to examine the mine, in a general way, and recommended it to Hamilton Smith, then in London, for the Exploration Company of London, with which he was prominently connected.

The mine had been shut down and was under water for about ten years, when it was brought to Hammond's attention by Alexander Stoddard, general agent of the New York Underwriters Agency. He and Hammond's friend, W. B. Bourn, of San Francisco, owner of the famous Empire mine near-by, became interested, on Hammond's recommendation, in supplying the money to re-open the property. At the time of the Hammond examination, there was little or no ore visible in the accessible workings down to about 1000 ft. on the incline.

The vein had been faulted and the surface plant removed. Under the Hammond regime, the workings were unwatered, the incline-shaft sunk, and drifting and cross-cutting carried on. New ore-ground was rapidly opened up, and an old stamp-mill was leased, about one mile away. The proceeds of this small plant soon enabled a more extensive development plan to be carried out, and a new 30-stamp mill was erected. About this time Hammond was general manager of the undertaking. At this stage in the company's affairs, Hague happened to be visiting Hammond at Grass Valley, and was enabled, through Hammond, to purchase the controlling interest in the company from Bourn and Stoddard, Hammond remaining manager and consulting engineer, but later devoting himself to the development of the Bunker Hill & Sullivan, in Idaho. The period in point was an interesting as well as critical chapter in the history of this great Grass Valley gold mine, and there was then call for some real mining courage and sagacity, to re-discover the mine, as it were, and put it on the way to future success.

New York, January 4. F. G. CORNING.

[The main subject of the interview was Mr. Foote and his career, not the North Star mine.—EDITOR.]

Rich and Poor Zones

The Editor:

Sir—The interesting and inspiring contribution of W. J. Loring relating, in your issue of November 27, his experience of finding poor zones and enrichments alternating with each other in the Plymouth Consolidated, brings to my recollection a remark, made to me personally, regarding the early history of the Great Boulder mine in Western Australia, by Richard Hamilton, the manager, who has, with such pronounced success, continuously guided the fortunes of that famous property almost since its discovery some seven and twenty years ago.

"When we went below five hundred feet," said Mr. Hamilton, "I really believed that the bottom had dropped out of the mine and my fears continued until we reached the 1200-ft. level, where an orebody was discovered almost identical with that which we had been working above." And so, by operating on a sound policy of maintaining development work well ahead of milling requirements, rich zones continued to be disclosed in sufficient number to compensate, in a large measure, for what, by comparison in value, might appear to be disappointments. The result is that the mine has flourished and, all these years, continued to furnish its fortunate shareholders with consistent dividends.

Even the old Lake View Consols mine, of Westralia's ton-of-gold-per-month fame, which reached a depth of 1950 ft. at the time when I was superintendent and which then disclosed no ore of payable grade below the 1750-ft. level, is, once again apparently, showing some signs of renewed hope and encouragement. Five winzes, each from 50 ft. to 150 ft. deep, have been sunk below the 2100-ft. level, at present the bottom, and, according to

latest report, assays as high as \$20 per ton (not in present-day currency but in real old-time metallic money) have been obtained, attractive enough to cause a resumption of sinking the main shaft to 2300 feet.

After all, a mine with a successful past must be considered of greater value than the result of sampling its lowest poor level would really indicate.

W. E. SIMPSON.

Boston Creek, Ontario, January 6.

Institute Affairs

The Editor:

Sir—At a time when an earnest effort is being made to persuade engineers to participate more actively in public affairs in order to ensure that public business shall be administered efficiently, it is particularly unfortunate for a great engineering society to be so mismanaged as to have its expenditures exceed its easily determinable income. One of the many sins which we charge up against the politician in his administration of public affairs is that he proceeds without any proper budget system.

The first thing which the Institute should do is to see to it that its officers cut down expenses until they come within its income. The deficit has not been created by the membership. The responsibility rests with the directors, who should be held personally responsible for the policy which they have pursued. The suggestion that \$5 should be considered as payment for the monthly publication, 'Mining and Metallurgy', is particularly unwelcome, as there seems to be no excuse for this publication. The technical press has always served the profession to its great satisfaction. Any matter which the Institute wishes to put before the public could be equally well or better presented through the regular journals of the profession.

All that the rank and file want of the Institute is the regular publication of carefully edited technical papers. If the editorial and publishing function were wisely discharged, the number and size of papers could be kept within reasonable limits, the monthly magazine would be entirely suppressed, and no deficit need exist.

Our profession should not be degraded to a condition of meeting expenses by passing the contribution-box, and our debasement is only added to when the Secretary asks for subscriptions which will, if paid equally by all members, amount to several times the amount necessary to be raised.

It is more than ever apparent that we need so thorough a house-cleaning in the New York office as will so completely remove the beam from our own eye that we shall have a right to assist in removing the mote from the eye of public business.

A MEMBER.

Palo Alto, California, January 14.

STATISTICS show that exports of oil from Mexico for the month of October totaled 17,300,000 barrels as compared with 8,060,000 barrels in January 1920. These figures are striking in view of the fact that in 1901 Mexico shipped out only 10,345 barrels.

The Present Status of Flotation Litigation

By T. A. Rickard

INTRODUCTION. In our issue of April 14, 1917, I told the story of the litigation arising in the Federal Courts out of disputes over the validity and scope of the patents owned by Minerals Separation, Ltd. At that time the Miami case had just been adjudicated by the Circuit Court of Appeals at Philadelphia, and the Supreme Court had disposed of the Hyde case. Since then the suit brought by Minerals Separation against the Butte & Superior Mining Co. has dragged its slow length through the three courts to final adjudication by the Supreme Court. This case may be regarded as a necessary sequel to the Hyde case. Meanwhile the Miami case has not yet gone to the Supreme Court; it is in the accounting stage, before a Master in Chancery, but it is expected that after the Master has reported finally, this case eventually will be submitted to the Supreme Court.

Two fresh suits have been started by Minerals Separation, namely, against the Nevada Consolidated Copper Company and the Magma Copper Company, the first operating at McGill, in Nevada, and the other at Superior, in Arizona.

BUTTE & SUPERIOR. This case was tried first before Judge Bourquin in the District Court of Montana and a decision was given on August 25, 1917.¹ The trial lasted from April 18 to May 15. The Court upheld the validity of patent No. 835,120 and the Butte & Superior Mining Co. was declared to have infringed this patent. It was found that throughout the period of infringement the defendant's process always involved the use of "a pyramid machine of seven cells in series, each cell containing a revolving perpendicular spindle and horizontal blades, and having two opposed spitzkasten". The result was violent agitation. At certain points in the flow-sheet there were, it is true, Callow or pneumatic cells, but at all times the pulp was first subjected to the rapid rotary agitation as described.

As to whether, after January 7, 1917, the addition of petroleum oil, to bring the total mixture to more than 1% of oil on the ore, took the defendant's operations outside the scope of the patent, the District Court decided that the petroleum oil added in the mixture "if not inert is ineffective, wasted, and injurious to the process and results", and that the pine-oil, used in substantially the same proportion as during the admitted infringement before January 7, 1917, was performing the same function as before; therefore, the substance of the patent having been taken, the defendant could not escape the consequences of infringement.

An injunction and accounting were ordered by the decree of the District Court, but the injunction was

stayed pending an appeal. This appeal was argued at San Francisco, before the Circuit Court of Appeals, on March 8, 1918,² and a decision was given on May 13, 1918.³ The Court was not the same as that which had heard the Hyde case, for Judge Gilbert was absent, but Judge Ross, who wrote the opinion in the Butte & Superior case, was one of the three who had sat in the Hyde case. The chief question considered was the proportion of oil used in the process covered by the patent. The majority of the Court, Judges Ross and Hunt, appear to have been impressed by a colloquy⁴ that took place between W. H. Kenyon, of counsel for Minerals Separation, and Justice McReynolds of the Supreme Court during the argument of the Hyde case. In consequence they held that the Supreme Court intended to limit the patent to five-tenths of 1% of oil on the ore, that being, in their opinion, the critical proportion that the Supreme Court had in mind when holding patentability to reside, among other things, in the use of a specific amount of oil "having a preferential affinity for metalliferous matter". Judge Morrow dissented, his opinion being that the patent was limited to 1% of any oil or oily liquid, and that the use of oil "in a quantity amounting to more than a fraction of 1%" was not an infringement upon the plaintiff's process.

This case was then taken, by writ of certiorari, to the Supreme Court, which gave its decision on June 2, 1919. The opinion⁵ was written by Justice Clarke, as in the Hyde case. The Court held, against Judge Bourquin, of the Montana District Court, that "petroleum and petroleum products are oils useful in this process of the patent", and it agreed with the minority opinion of the Court of Appeals limiting the scope of the patent to 1% of oil. I quote the last paragraph of the Supreme Court's decision:

"It results that the decree of the Circuit Court of Appeals that the respondent infringed the patent only when using one-half of 1% or less of oil on the ore must be reversed, and that its implied holding that the use in excess of 1% on the ore did not constitute infringement must be sustained. The case is remanded to the District Court for further proceedings in conformity with this opinion."

It will be remembered that the Butte & Superior company increased its use of oil to more than 1% after Jan-

²A description of the proceedings appeared in the 'M. & S. P.' of March 16, 1918.

³The full text of the decision will be found in the 'M. & S. P.' of May 25, 1918.

⁴See p. 379 of 'M. & S. P.' of March 16, 1916.

⁵See 'M. & S. P.' of June 21, 1919.

¹The opinion was recorded in full in the 'M. & S. P.' of September 29, 1917.

uary 7, 1917,* that is, almost immediately after the Supreme Court's decision in the Hyde case. The same Court now held that the company, by which Mr. Hyde had been employed professionally, had infringed the patent only when it used oil in the proportion of less than 1%. In arriving at its decision, the Court made the following findings:

1. That the new evidence was too meagre in amount and too unsatisfactory to modify the Court's conclusion in the Hyde case on validity.

2. That except as to the proportion of oil, defendant's methods were substantially those of the patent in suit, that is, as defined in the Hyde case, the agitation of the pulp "by beating air into the mass" so as to form "a peculiarly coherent" froth.

3. That petroleum products are oils "efficient and useful in the process", but not "as highly efficient" as pine-oil or other oils that in the record are called "frothing oils".

4. That the froth derives its power of flotation mainly from the inclusion of air introduced into the mass by agitation.

5. That the patent disclosure to which Minerals Separation must be limited is when a fraction of 1% of oil is used "in the manner prescribed".

6. That the term 'frothing oil' does not appear in the patent.

7. That "the patent is on the process, it is not and cannot be in the result", and the scope of the patentees' rights is limited "to the means they have devised and described as constituting the process".

These findings by the Supreme Court are important in their bearing upon further litigation. The idea of a frothing-oil† is rejected. So far as patent 835,120 is concerned, we have "oils, oily liquids, and oily substances having a preferential affinity for metalliferous sub-

stances". In this (Butte & Superior) case the type of operation considered was that of the Janney machine, in which violent agitation is obtained of the type of the Gabbett mixer. Naturally it was inferred by those using machines of the pneumatic type, such as the Callow cell, that they could escape the charge of infringement, for did not the Supreme Court state the essence of the patent in the following definition: "We have found that if a proportion of oily substance be considerably reduced . . . granulation ceases to take place, and *after vigorous agitation* [italics mine], there is a tendency for . . . metalliferous matter to rise . . . in the form of a froth or scum". Again, the Court said: "The froth or scum derives its power of flotation mainly from the inclusion of air bubbles *introduced into the mass by agitation*".

The Butte & Superior case was sent back to the District Court, in order that it might recast its decree in conformity with the decision of the Supreme Court. An accounting was ordered and an account was filed before Judge Bourquin by the defendant. Exceptions were taken thereto. At the same time Minerals Separation petitioned the District Court to adjudge Butte & Superior guilty of contempt for having violated the injunction issued by the Court, the contention being that Butte & Superior was *not* using more than 1% of oil mixture per ton, because a portion of the oil was returned with the middling to the head of the flotation machine from the fourth to the seventh Janney cells. After a hearing (in February 1920) Judge Bourquin dismissed the contempt petition, holding that this question had not been decided by the Supreme Court and that he therefore could not adjudge contempt upon a question that had only been half litigated by the plaintiff. Nevertheless, this is an important point, for, in most milling operations, a varying portion of the oil is re-used. The accounting in this case is still pending, no testimony having been taken as yet.

MIAMI COPPER COMPANY. This case was decided in the Circuit Court of Appeals at Philadelphia on May 24, 1917. The majority opinion was that the three patents in the suit, No. 835,120, No. 962,678, and No. 1,099,699, were valid and had been infringed.⁶ The minority opinion held that the first patent had not been infringed by the defendants' operations except when using the so-called first method. This case is rendered interesting by the fact that the Miami company used four methods successively; in the first it used a standard Minerals Separation machine; in the second, a centrifugal pump, a break in the circuit, a Pachuca tank, and Callow cells; in the third a Pachuca tank and Callow cells; and in the fourth a bucket-elevator and Callow cells. The fourth did not appear in the record, the majority opinion concerning itself only with the three previous methods, all of which it adjudged to have infringed patent No. 835,120. The main question was whether the agitation in the Miami mill was of the violent and persistent kind covered by the patent, the Court deciding that the centrifugal pump and the Pachuca tank together produced that kind of agita-

*In a statement dated November 22, 1919, and filed by the Butte & Superior company on the accounting, the varying proportions of oil are given in detail. From September to December 1915 less than $\frac{1}{2}$ % was used; from January 7 to January 29 the percentage was well above 1%; from January 30 to February 9 it was less than 1% but more than $\frac{1}{2}$ %; from February 12 to March 31 it was again in excess of 1%, and so on. An interesting question arose, Minerals Separation insisting that the oil in the circulating load should not be included when determining the proportion of oil used vis-a-vis the patent. The oil in circulation, which is returned to the head of the mill, amounts to several pounds per ton on the ore. The Minerals Separation people contended that the Butte & Superior was in contempt of the injunction because it has added only 18 lb. of fresh oil during certain periods, and that the proper interpretation of the Supreme Court's decision required the addition of at least 20 lb. of fresh oil in the process in order to escape infringement. Judge Bourquin, of the Montana District Court, decided that there was no proper justification for the contention that the Supreme Court had so decided and advised Minerals Separation to appropriate subsequent procedure in the case with a view to having the question determined. The answer hinges upon effectiveness of the oil in circuit, and as to that there seems to be little doubt among those using the process.

†It is not an oil that froths; it is an oil for making froth.

⁶See 'M. & S. P.' of June 16 and 23, 1917.

tion. The fourth method, from which these devices were omitted, was not discussed because the Court "cannot consider and adjudge with propriety or authority a process with respect to which the plaintiff has had no opportunity to produce testimony and which was not embraced in the decree [of the District Court] we are reviewing". This was unfortunate for the Miami company, which, since the case was first tried in the lower Court, has disregarded the infringing devices. The company managed its case badly, for the real name of the Pachuca tank is the Brown agitator, and to contend that the passage of the pulp through a Pachuca did not 'agitate' was unwise.

Since this case will be referred again to the Circuit Court of Appeals, and possibly to the Supreme Court, after the Master makes his report on the methods that have been used in the Miami mill since October 1, 1915 (the date at which the third method was discontinued), it is well to analyze the majority opinion, by Judge Woolley, because, obviously, it bears upon the highly important question whether aeration of the pulp through a porous medium, as in the Callow cell, constitutes infringement of No. 835,120.

It is to be noted, in the first place, that the Court of Appeals, following the Supreme Court in the Hyde case, overruled the District Court when it said that the patentability of 835,120 resides in the mere diminution of oil. Judge Woolley interpreted the Supreme Court's decision as finding patentability in the co-action of a specific proportion of oil and a special kind of agitation, the air bubbles being introduced into the pulp "by an agitation greater than and different from that which had been reported to before". The Miami company admitted the use of less than 1% of oil and that the lifting force in its three methods was air; the issue therefore was whether the agitation it produced was "greater than and different from" the prior art. It was admitted that a froth was formed, but it was denied that it was the same kind of froth as that of the patent or the product of the kind of agitation described in the patent.

Setting aside the first method employed at Miami as being obviously experimental, it will be noted that in considering the second method Judge Woolley decided that the centrifugal pump sucked air and that the blow from the pump-paddle produced the agitation of the patent to violence if not duration. He found some aeration resulting from the splash of a break in the circuit; likewise he found agitation and aeration in the Pachuca tank. In normal operation of the second method the pulp did not come to rest in the Pachuca but was delivered by launders to Callow cells. The Court found that the entrance of air through the porous medium at the bottom of the Callow cell caused some measure of agitation but it was "not even approximately of the violence and duration of the agitation of the patent". The Court proceeded to say that the defendants had argued the case largely though its process consisted solely in passing thoroughly mixed but quiescent pulp directly into Callow cells, where it received its first and last aeration without previous or present agitation, resulting in a metallurgical

froth quite different from that of the patent. Judge Woolley could not find that the record justified this argument; he said:

"If the only agitation to which the pulp was subjected (after such agitation as in the prior art was necessary to mix the oil and ore) was the agitation of the Callow cells, we would not say that that agitation amounted to or was the equivalent of the violent agitation of the patent disclosure and constituted infringement; . . . the Callow cells were not the whole process but were merely the last of four distinct parts of the process, the other three being the process of the patent or its fair equivalent. Having used the process of the patent in the first three steps [centrifugal pump, break in circuit, and Pachuca] in developing in the pulp the potentiality of the critical quantity of oil and air, and in bringing the pulp to the point where, if permitted, it would produce the result of the patent, we feel that the defendant cannot escape infringement by taking an additional step, even though that step if taken alone avoids the patent."

The foregoing quotation is the crux of the decision by the Court of Appeals in the Miami case; it shows what a blunder was made in adopting the unnecessary use of the machines that infringed the patent, for the Court, referring to the patentees, said that "agitation was the secret by which the principle of their discovery could be unlocked and used".

In the third method, the centrifugal pump and the break in the circuit were omitted, the Pachuca being preceded by a bucket-elevator, which performed the function of the centrifugal pump in raising the pulp. The oil, it is true, was added ahead of the elevator, but, without commenting upon the action of the elevator, the Court held that this method also involved an agitation similar to that of the patent and therefore constituted infringement.

The second and third methods were discontinued in September 1915, four months after the submission of the case to the District Court, just one year before that Court handed down its opinion, and twenty months before the Court of Appeals pronounced its decision. For most of the time between October 1, 1915, and May 24, 1917 (the date on which the Court of Appeals issued its decision), the Miami company used the fourth method, consisting in the employment of the bucket-elevator, launders, and Callow cells, the mixture of oils being added at the foot of the elevator. Although the flow-sheet of this practice was before the Court in the form of a blueprint and the questions involved in these operations were argued at length, the Court felt itself restricted by the record so that it could not "consider a process with respect to which the plaintiff had had no opportunity to produce testimony, and which was not embraced in the decree under review". Had the Court been of the opinion, as has been argued by Minerals Separation in later proceedings, that the second and third methods were of such scope as to include the Callow cell, there was enough in the record to warrant a consideration of this question. In discussing the third method, the Court reproduced in

its opinion the blueprint mentioned above and described an experiment in which one part of the Miami mill was operated by the third method and another part by the fourth method. The Court said:

"In the experiment, one group was operated with the Pachuca tank as planned. In the other, the Pachuca tank was cut out and the pulp conveyed directly from the elevator to the cells. The result was no apparent difference in the action of the pulp and little difference in the assays of the metal recoveries, that difference, curiously enough, being in favor of the group in which the Pachuca tank was not used. The evidence of the fact and of the effect of this experiment was not contradicted, except, perhaps, by the defendant itself, by returning at once to its previous practice of using both Pachuca tanks, and in pursuing that practice to a time beyond the trial. This fact places the Third Process' in the position of the Second, where we have found that agitation and aeration of the Pachuca tank is the agitation of the patent, and amounts to infringement."

From the foregoing it is not quite clear whether the Court held that the method without the Pachuca avoided infringement, although the reference to the contradiction of the experiment by the return to the use of the Pachucas might warrant such an inference. In the direct testimony and cross-examination there was an account of the operation on a milling scale of the elevator and Callow cells, precisely as described under the so-called Fourth Process, and it is unfortunate therefore that the Court held itself unable to adjudge this point, so vital to the suit, and to the legal status of the Callow cell under the first patent, No. 835,120. Moreover, the status of the Callow cell under the second (soluble frothing-agent, No. 962,678) patent was not discussed by either the District or the Appellate court in the Miami case. This is a curious omission. The Court of Appeals had considered the use of the Callow cell in connection with the first patent, and found it not trespassing upon the agitation of that patent; if a different measure of agitation was intended to be ascribed to the second patent, and there was lack of proof of the agitating effect of the bucket-elevator under either of the patents, it was open to both Courts to apply the measure of agitation of the second patent to the Callow cell and thereby determine where it came within the scope of that patent. The question of the action of the Callow invention was known to the Court of Appeals to be the important issue involved in the lawsuit, and if there had been any intention of bringing the Callow cell within the scope of the second patent, it was to have been expected that the Court would so express itself, instead of leaving this vital question undetermined. In default of a clear pronouncement on this point, it may be assumed that the Court meant what it said when it found the difference between the first and second patents to be in the character of the frothing-agent used, and that in the second, as well as in the first, patent "the decision turns

upon the kind and degree of agitation employed by the defendant". Since the third patent in suit is concededly an amendment of the second patent, it must be limited or fall with it.

After the decision of the Court of Appeals, in May 1917, the Miami company was given time to decide whether it would present a petition to the Supreme Court for a writ of certiorari preliminary to a further review of the case by the court of last resort, and, after due consideration, the defendant company concluded to accept the decision of the Appellate Court as being substantially in its favor, any action in the nature of an appeal therefrom having the appearance of an attack upon that favorable decision. Accordingly in August 1917 the Miami company notified the Court of Appeals of its intention not to apply for a writ of certiorari, whereupon the mandate of that Court issued and the decree of the District Court was pronounced, together with an injunction restraining the Miami company from continuing the practices that infringed the patents in suit.

In accordance with the original order entered by Judge Bradford, of the District Court, the case was referred to William G. Mahaffy, as Master, to obtain an accounting of the profits derived by the Miami company in consequence of its infringing practices. Late in 1917 the Master ordered the Miami company to file its account, which was done in due course. Minerals Separation filed its exceptions to this account and thereby raised the question as to whether the milling practice subsequent to the first, second, and third methods, as considered by the Court of Appeals, was or was not a colorable departure from the declared infringements. In support of its contention that the later practice was merely such a colorable departure, Minerals Separation called as its witness R. B. Yerxa, assistant mill-superintendent to the Miami company, and examined him for 30 days in connection with the introduction of 80 exhibits, representing every milling and experimental operation performed in the mill from September 1915 to the date of the examination. Mr. Yerxa's testimony covers 625 pages. At the request of Minerals Separation, his testimony was interrupted in order to allow a visit of inspection to the Miami mill by the Master, with counsel and experts for Minerals Separation. This visit extended over four days.

On November 26, 1919, more than a year and a half after the taking of testimony had been begun before the Master, and after 2500 pages of testimony had been accumulated, Minerals Separation made a motion for leave to file a Supplemental Bill, the avowed purpose of which was to take from the Master the question whether the later operations of the Miami company were or were not infringing. Two months later, on January 27, 1920, the Court denied this request, on account of certain defects in the proposed Supplemental Bill, and at the same time indicated its opinion that the investigation into the later milling operations came properly before the Master.

On May 4, 1920, Minerals Separation filed its petition in the District Court, praying that the Miami company be adjudged in contempt, as having violated the injunc-

¹I have used 'method' instead of 'process', the former term suggesting more correctly a way of performing a process rather than a different process.

ion of the Court, and that a further injunction be issued to restrain the company from the practice it had adopted after discontinuing the so-called Third Process. On May 4 the Miami company filed its answer denying that the said operations were infringing and asking that the petition be dismissed. This motion was argued before the Court on June 15, and on July 23 the Court dismissed the petition for contempt. Judge Morris, of the District Court, in his opinion, stated that "in view of the nature of the new processes used by the defendant as charged by the petition . . . the plaintiff must obtain the relief to which it is entitled, if any, touching the new processes, either through the proceedings now being had before the Master and the decree to be entered thereon, or by a new bill, and not otherwise". On the same day therefore Minerals Separation made a motion for leave to file a supplemental Bill, praying that Minerals Separation North American Corporation be made a party to the cause, and, although objection was made to this, the Court decided to grant the request, "but without prejudice to the defendant to renew its objections, in a manner when suitable, to the bill when filed, if it be so advised". An order accordingly was made on July 22. Four days later Minerals Separation asked for leave to file a second supplemental Bill, the purpose of which was the taking of the investigation of the Miami company's later practice from the Master, and the trial of the same before the District Court. This was denied, on August 11, 1920. Whereupon Minerals Separation took an appeal on the two orders (of July 23 and August 11) to the Court of Appeals, and the Miami company filed a motion to dismiss the appeal, and this matter was set for argument at Philadelphia on November 9. A month later, on December 9, Judge Woolley pronounced the decision of the Court of Appeals, affirming the orders of the District Court and holding that the modifications or changes made by the defendant in its milling practice since September 15 were not plainly mere colorable equivalents of procedures that infringed. Judge Woolley held further that the practice of issuing supplementary injunctions is not to be adopted in the Third Circuit and that "the remedies against infringement after decree are those which now prevail, namely, damages and profits on accounting, attachment for contempt, and original bill; in the last the patentee's right to injunctive relief is fully preserved to him". The Court stated: "We have read and carefully studied the entire record . . . We shall not restate the law of the case, but shall address ourselves solely to the new facts. These embody at least eleven new procedures or modifications of procedures charged to be infringements because equivalents of the infringements found by this Court in its decree. The processes decreed to be infringements were made up of several steps in which it was found, speaking most generally, that infringements were completed before the pulp had reached the Callow cells. In none of the eleven modified processes, again speaking generally, is there a centrifugal pump or a 'break in the circuit' or a Pachuca tank, means or steps held potential in the infringements found. In the

later modified procedures, Callow cells are employed exclusive of and inclusive with other means, in some instances with no prior agitation, in other instances with prior agitation without aeration, in still other instances with prior agitation and aeration, indicating agitation in degrees varying as greatly as the adjectives used in describing it; but whether in any of them there is agitation of the kind, in the degree, and for the duration contemplated by the patent is not so clear and unclouded as to make the newly alleged infringing procedures free from doubt and to warrant the extraordinary remedy of supplementary injunctive relief . . . To avoid the appearance of affirming the Court's decree upon the negative quality of a finding that we discern no error in its order, we go farther and say, that, having made the law of the case we are presumed to know what it is, and that, applying the law to the facts, which, on the defendant's motion to dismiss are regarded most favorable to the plaintiffs, we would have made the same disposition of the case had we been sitting in the District Court when the application for a supplementary injunction was made. We are of opinion therefore that the order or orders of the District Court should be affirmed and the case be proceeded with expeditiously and in a manner consistent with the law."

On May 26, 1920, the Miami company petitioned for leave to file a supplemental bill in the nature of a bill of review. The company took this step on account of the discovery of "an unpublished book in manuscript form", written by Messrs. Sulman and Picard in 1906. This treatise, a copy of which was found in the possession of T. J. Hoover,* to whom it had been given by the authors early in 1907, contained evidence tending to show that patent No. 835,120 was limited to a process of concentration in which less than 1% of oil was added to a freely flowing pulp and the mixture subjected to rapid rotary agitation, until the sulphide mineral formed in a froth. It was also the contention of the Miami company that this treatise, entitled 'The Theory of Concentration Processes Involving Surface-Tension', disclosed the point to which the art had advanced, as far as known to the patentees, prior to the alleged date of invention, and that this state of the art left nothing open to invention save the single element of the "whipping in" of external air by rapid rotary agitation. It is apparent from the treatise that Messrs. Sulman and Picard knew that froth had been produced in the Potter and Delprat processes without the use of oil, the lifting force being solely the gas generated within the pulp by the action of acid on carbonate minerals; that they were well aware of the fact that Froment had produced froth of the same character, in the same kind of process, with the addition of a proportion of oil so small as only to film the particles of mineral, so that the film, to all intents and purposes, became part and parcel of the particles themselves; that in the Elmore vacuum process the same kind of froth was produced by using a similarly small proportion of oil,

*M. Hoover's affidavit was published in the 'M. & S. P.' of June 19, 1920.

the lifting force being air drawn out of solution by the application of a vacuum; and, further, that the same result could be obtained in a process using the same small proportion of oil by passing a current of air through the pulp in the form of bubbles, as disclosed in the so-called bubble patent, No. 793,808. The treatise indicates that the patentees, at the time (March 1905) of their supposed invention of the process covered by No. 835,120, were aware of all these facts, which limited their patent, in their own words, as a "mere practical application of the Froment principle", wherein air was introduced into the mass of pulp by whipping in external air by rapid rotary agitation. Thus the argument for the defence comes back again, much reinforced, to the one brought forward in the first trial of the Hyde case in Montana, eight years ago.

The Court denied this petition of the Miami company, but stated: "In so doing, we express no opinion as to the relevancy or competency of the subject-matter of the petition on questions arising on accounting." This apparently indicates the belief of the Court that the whole matter could be settled in the proceeding before the Master or in a new suit begun by an original bill, and that the proper way to introduce this new evidence was not in a re-opening of the original case but in the proceedings on the accounting, which, in the end, of course, will go back to the Court of Appeals, or be adjudicated in the course of a new suit under an original bill.

Meanwhile, although seriously impeded by the numerous attempts to cause the investigation into the later milling methods to be removed from the accounting proceedings, the Master has continued to take testimony, but as yet the *prima facie* case on the accounting has not been completed.

NEVADA CONSOLIDATED. On September 9, 1919, Minerals Separation North American Corporation and Minerals Separation brought suit against the Nevada Consolidated Copper Co. in the District Court of Maine, southern division, on patent No. 835,120. The defendant, in answering, raises the issue of validity and denies infringement. This case may be heard some time this winter. On February 16, 1920, Minerals Separation brought suit against the same mining company on patent 962,678 (the so-called soluble frothing-agent). The defendant again denies validity and infringement. It is expected that this case also will come up for trial during the coming winter.

It is interesting to note that in these Nevada cases the plaintiff is claiming that pine-oil has certain soluble fractions, and that the use of pine-oil constitutes an infringement of both patents, 835,120 and 962,678. It remains to be seen how Minerals Separation will square its present position with the testimony in the Miami case, wherein its expert, Dr. Leibmann, said that pine-oil, for all practical purposes, was insoluble, and it remains also to be seen how Minerals Separation will deal with the Supreme Court's decision in the Butte case where it was held that pine-oil was "an oil having a preferential affinity for metalliferous matter" within the description of patent

835,120. The legal definition of 'solubility' will be awaited with interest, likewise the juridical effort to distinguish between the use of the term in chemistry and in metallurgy respectively.

MAGMA. On January 10, 1920, the two Minerals Separation companies filed suit against the Magma Copper Company, also in the District Court of Maine, southern division. In this suit the same patents, 835,120 and 962,678, are involved. The defendant denies infringement and questions the validity of the second patent.

In this case, as in the Nevada cases, there will be presented squarely to the Court the question whether or not the Callow or other pneumatic cell is an infringement of either patent. In the mills of both companies the operations have been excluding any prior agitation other than is necessary to mix the oil with the ore, so that the agitation described in these patents, if present, must be found within the pneumatic cell. The decision in these cases ought to settle definitely the validity and the scope of the first patent, both as to the character of the frothing-agents and the meaning of the agitation prescribed in the claims. The validity of the patent for a soluble frothing-agent should be fought to a finish, and it should be ascertained what is a "soluble frothing-agent" and whether it is covered by the description of the oil of the first patent; and if not, we should be told the meaning of the phrase "agitating the mixture to form a froth".

As yet Minerals Separation has not brought suit against any other of the alleged infringers; the cases now pending raise practically all the important questions left in doubt by the precedent litigations, and while Minerals Separation may find it necessary to bring additional suits to prevent its rights from lapsing by limitation, it would appear certain that the decisions in the several cases pending should determine definitely the extent of the monopoly that Minerals Separation is to be permitted to exercise by law.

To FACILITATE the development of the Flin Flon copper deposit in Manitoba, involving the building of a railway approximately 100 miles long, the erection of a mill and smelting plant at a cost of about \$3,000,000, and the development of water-power with 35 miles of transmission line at a cost of not less than \$2,000,000, the Canadian government has issued an Order in Council making important changes in the mining regulations. The regulation requiring that all ores shall be treated and refined in Canada is set aside, owing to the cost that would be involved in shipping the blister-copper for final treatment to the Trail smelter in British Columbia, and permission is granted to export blister-copper, the product of the mill and smelter, for a period of ten years unless in the meantime facilities have been established in Canada for the electrolytic refining of this product as cheaply and efficiently as elsewhere. It is also provided that products of the Flin Flon mine, in which the gross recoverable metal is valued at less than \$10 per ton, and are smelted in Canada, shall be exempted from royalty for ten years from January 1, 1921.

THE SOUTH LODE OF RIO TINTO, LOOKING EAST

THE SAME, LOOKING NORTH

Pyrite in the Huelva District, Spain

By Courtenay De Kalb

***INTRODUCTION.** Nearly the entire output of pyrite the copper production, which directly depends upon the in Spain is derived from the province of Huelva. Out operation of the pyrite mines, as follows:

Copper Production of Spain, 1918				Corresponding	Total value,
Merchantable	Source	Kilogrammes	Pounds avoirdupois	tonnage of ore, metric	pesetas
Cement copper	Huelva, from leaching	22,642,381	49,813,238	1,745,796	65,555,868
Blister copper	Huelva	18,610,000	40,942,000		43,054,462
Cement copper	Sevilla, from leaching	799,000	1,757,800	15,201	937,400
Copper matte	Cordoba	1,453,000	3,196,600		2,074,500

of a total production, in 1918, of all classes of pyritic ores, which were valuable in part for their sulphur content, 1,597,675 metric tons, or 96%, came from that Province.

In addition to the foregoing, it is of interest to note

***Abstract from a report prepared for the Bureau of Foreign and Domestic Commerce, Department of Commerce, Washington.**

It may be well to mention at this point that the Rio Tinto mine alone, which is the heaviest single producer in the Province, was mining, in July 1919, at the rate of 5000 tons per diem, with a payroll embracing about 9000 men in all positions. Of that quantity, 4000 tons would be classed as sulphur ore, that is, it contained from 46 to 47% of sulphur. The remaining 1000 tons was highly silicious, but rich in copper, and did not

IN THE BIG PIT

SOUTH END OF RIO TINTO

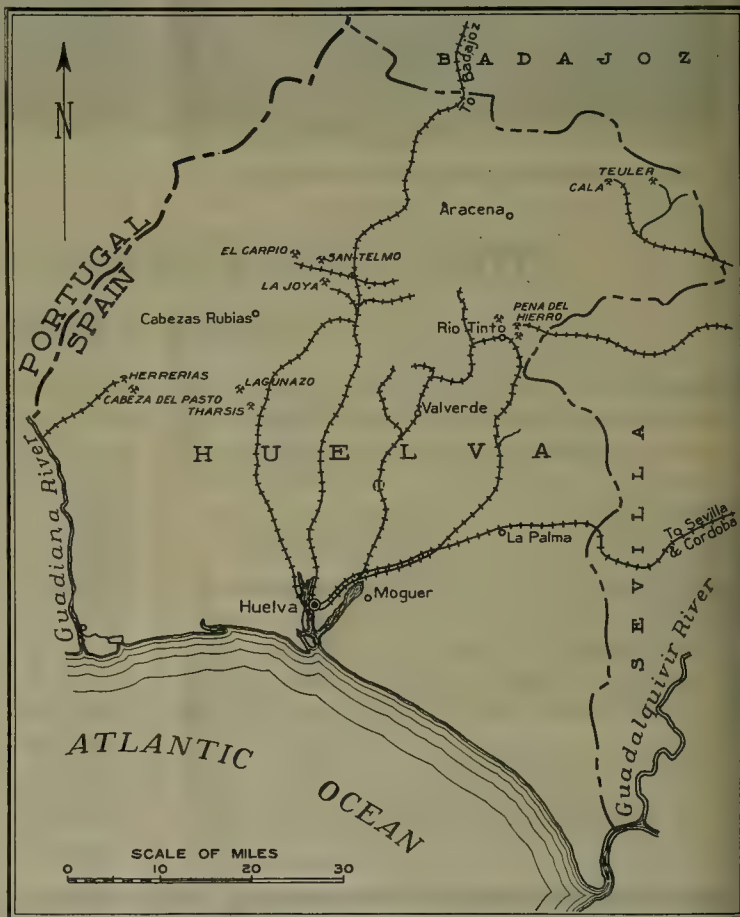

figure in the pyrite market. The Tharsis mine, near the centre of the Province, produces considerably less than the Rio Tinto, though it is now prepared to mine and ship 1,000,000 tons yearly.

In the Huelva district it is customary to mine large tonnages of ore, regardless of the existing demand in the pyrite market, and to store this in leach-piles on the surface. As will be shown later, the copper is perfectly extracted, and at a low cost, by a method of leaching. At the same time the removal of this copper results in raising the sulphur content of the residual pyrite, rendering it superior as a 'sulphur ore'.

Following this system, therefore, and considering that, after the first few months, the cost of taking care of a leach-bed is reduced to a low figure, and also that copper in appreciable quantity continues to issue from a bed for periods as long as ten years, while pyrite remains essentially uninjured and loses a total rarely in excess of 10% of its weight by oxidation, it is apparent that storage does not represent a heavy expense. The cost of mining, including overhead charges, is repaid by the copper recovered in the first few years of leaching. Therefore it is not necessary to charge interest, except for a brief period, against the ore stored in the leach-beds. The copper recovered, even from the seventh to the tenth year, will pay a profit on the cost of taking care of the bed. Accordingly, the liquid assets of a company are increased by accumulating ore in this manner. While it remains in the mine it is a potential asset; when transferred to the surface it becomes a liquid asset as soon as it has been long enough in the bed to have yielded above 80% of its copper, with a corresponding increase in the proportion of contained sulphur. It is then ready for market as a sulphur ore. Whatever is obtained for the sulphur, and for the residual cinder, considered as an iron ore, above the cost of handling and transportation, appears to me a net return. This would probably be denied by the operating companies in Huelva, but investigation reveals the facts to be as stated. It is to the credit of the Province and of the producing companies that it is so. It displays the strength of their position. They can afford to wait for unfavorable market conditions to change, and in the end they will be found to hold a commanding position with reference to the production of sulphuric acid. In the last analysis the sulphur obtained by means of the unique system of ore-treatment in vogue at the mines of Huelva is as much a by-product as the sulphur that may be utilized in the fume at smelting works.

As a result of the peculiar character of the Huelva ores, which admits of their being mined and stored on the surface and of yielding a profit at the same time, it is advantageous for an operating company to accumulate such stocks. It pays to do so for the sake of the copper produced, regardless of whether the ore be sold for its sulphur content or not.

STOCKS OF ORE. I have endeavored to ascertain the amount of such ores now mined and stocked in the leach-beds in the province of Huelva. For the most part, such

THE PROVINCE OF HUELVA, SPAIN

figures are closely guarded; the total, however, appears to be not less than 25,000,000 tons, of which about 15% is clean leached pyrite, averaging between 47 and 50% sulphur, a large part of which is sufficiently leached to be ready for shipment; 40% is low-grade ore, averaging above 35% and below 40% sulphur, which will require to be concentrated before it can be sold as a sulphur ore; and the remainder is above 20% and below 35% sulphur, usually higher in copper than the high-iron-sulphur ores, but which will probably never be used as a source of supply for concentration.

According to the official report of the Ministerio de Fomento, in August 1917, the Rio Tinto company has

18,540,000 metric tons of ore stacked in the leach-piles.

Estimates of tonnages developed in the mines are almost impossible to obtain, the mine managers being reluctant to divulge such figures. At some of the smaller

million tons developed; the Cuchichón (in the Sevilla portion of the district) is credited with 6,000,000. The reserves of the Tharsis company exceed 100,000,000 tons. The tonnages developed will enormously exceed the quantity mined and stored in the cementation beds. The total ore in sight, actually developed and ready for extraction, will apparently exceed 230,000,000 tons, of which 56,000,000 is in the Rio Tinto alone. The outlook for developing still greater tonnages in the Province is excellent. This will be discussed later.

THE PYRITE ZONE, within the province of Huelva, is 25 miles wide from north to south, and 50 miles long from east to west. It continues eastward into the province of Sevilla for at least 30 miles to the important mining town of Aznalcóllar. The zone also extends over 40 miles into the neighboring republic of Portugal to the town of Ajustrel. The pyrite area, therefore, is at least 120 miles in length. Throughout this zone is found an infinitude of diabase outcrops, constituting a parallel series. These intrusions are traceable continuously on the surface, but appear at intervals following the same general direction, having apparently been dikes that either reached the surface only at places, or have been disclosed by erosion at various points. The trend of these diabase dikes averages about N. 70° W., varying locally between E.-W. to N. 75° to N. 75° W. The orebodies conform to the direction of these dikes of basic volcanic rock, and are commonly associated directly with them, sometimes being found wholly within the basic rock, although for the most part they lie on the contact between the diabase and the enclosing slate.

The slate associated with the orebodies is of Silurian age in places, and in others sub-Carboniferous. The boundary between the Silurian and the Lower Carboniferous areas is usually not clearly defined, and fossils are rarely found, so that it is difficult to establish the identity of the geologic horizon. This is evidently of small economic importance. The famous Tharsis mine is in sub-Carboniferous slate; the Rio Tinto likewise, fossils being found at that point, especially at the San Dionysio workings; the La Joya-San Telmo-Carpio group is in Silurian; the Herrerias and Cabeza del Pasto are on the indeterminate border-line between rocks of these two ages. It seems to exert no influence upon the ore deposition which formation the intrusive rocks penetrate, despite the fact that the sub-Carboniferous slate generally contains a considerable amount of carbonaceous material, which is frequently present in the form of graphitic zones of marked persistence, following the cleavage-direction of the slate. Neither at the Rio Tinto, nor at the Herrerias, 50 miles to the west, is unaltered or partly replaced slate found in the ore, but nodular masses of pyrite, identical in character with the main orebodies, are sometimes seen in the slate. On the other hand, along the south wall of the great orebody in the San Dionysio mine (Rio Tinto) porphyry tongues (apophyses) are seen extending to considerable distances into the slate. These are always highly altered and sericitized,

THE RIO TINTO

THE HERRERIAS MINE

LOADING ORE ON THE GUADALQUIVIR

mines the officials in charge admitted having developed tonnages ranging from 500,000 to 1,000,000. The Herrerias has 1,000,000, the Cabeza del Pasto is still more important; the Peña de Hierro probably has several

and often contain notable amounts of disseminated copper sulphide in the form of sooty and fine granular chalcocite. On the north wall, in contact with the volcanic intrusive rock, the boundary of the ore is not as sharply drawn as it is on the south side in contact with the slate, and the ore and volcanic rock are greatly intermixed, many veins and masses of pyrite being traversed before the main orebody is reached. There is also a great deal of sericite on the side adjoining the porphyry. This stands forth prominently on looking into the great south open-cut, 590 ft. deep, at the Rio Tinto mine. The sericitized material clearly marks the limit of the orebody by a line of white, and also makes prominent the foot-wall along the south side of the terraced open-cut.

The intrusive rock crosses the slaty cleavage at a small angle, the slates always bearing more northerly. The slate has, quite independently of the planes along which it splits (fissility), developed two sets of joint-planes, one inclined toward the south and the other nearly horizontal. The slaty cleavage dips at an angle of nearly 60° from the horizontal, and this is crossed by a sub-cleavage or rift. The slaty cleavage generally dips toward the ore and the strike is more northerly than the trend of the orebodies.

According to George Wyndham Gray, superintendent of mining operations at the Rio Tinto, the so-called *ofitas*, or dioritic to diabasic rocks, are not derived from a basic magma, but represent altered segregated portions of acid magmas. As seen in the vicinity of Rio Tinto these dikes are greenish in color, like partly altered diabase, but Mr. Gray informs me that on penetrating them for some distance they prove to be hard silicious rocks of a 'felted' structure, and are not crystalline or fine-grained. The evidence at the San Dionysio mine indicates alteration from a basic rock (a point that can be definitely determined by microscopic examination of specimens), but I noted quartz inclusions in the form of rounded masses, such as frequently occur in quartz-porphyry. This, however, is not decisive, since these quartz inclusions are equally characteristic of the relatively basic dacite. I must defer to the longer study of the Rio Tinto deposit made by Mr. Gray, and it may be necessary to admit the association of this, the largest known pyritic orebody in the world, with volcanic rocks of an acid (silicious) type, but the least altered specimen that I was able to find between the San Dionysio and the north group of orebodies had the appearance of an altered silicified semi-basic rock.

It is an interesting fact that the iron deposits of Spain, whether existing as pyrite, as oxides, or as carbonate, seem to be associated universally with basic, and often with ultra-basic intrusions. This suggestion of a common genetic basis for most of the iron deposits of Spain is open to question, but careful study of the entire area will, I believe, demonstrate that such a hypothesis is worthy of consideration. It is noteworthy that on going northward from the centre of the pyrite belt in Huelva the proportion of iron in the ore-forming solutions ap-

parently has been progressively greater than the sulphur, while the copper has remained rather uniform. Thus, at the Cala mines, and at the Teuler a few miles farther north-east, are found great masses of magnetite replacing diabase, with irregular aggregations of pyrite and chalcopyrite, which at places bring the material within the classification of pyritic ore, as which it is reported in the statistics of the Consejo de Minería. Proceeding northward, the iron ores of Badajóz and Cáceres are found, with only moderate quantities of pyrite disseminated through them. I believe that the pyritic orebodies of Huelva, Sevilla, and south-western Portugal may represent one phase of a general phenomenon that is observed over the larger part of the Spanish peninsula where the intrusion of basic rocks has resulted in the formation of great iron orebodies.

At the Rio Tinto the deposition of ore has taken place on an enormous scale, and extensive gossans existed as a guide for the early miner. The alteration has been so profound that it is extremely difficult to obtain a sample of the igneous rock accompanying the ore that is fresh enough to admit of identification in the field. Proceeding westward, the outcrops of the orebodies become more and more obscure, until, at the Herrerias, no outcrop at all is seen, and the existence of ore is indicated on the surface only by faint lines of discolored material, whitish, yellowish, pinkish, and often with small discontinuous outcrops of quartz veinlets containing casts of pyrite crystals, and occasionally with some remnants of unchanged pyrite. It was upon such indications that the original exploratory shafts at Herrerias were sunk. The first shaft, which reached a depth of about 200 ft., failed to disclose any ore, and a cross-cut, which later proved to have come within 15 ft. of the upper end of a powerful orebody, also gave negative results. Subsequently an English company followed the indications of the lode westward, about a mile, to a prominent brilliantly iron-stained hill, known as Cerro Colorado, and expended at this point about \$400,000 in a vain search for ore. Undeterred by these failures they returned to the Herrerias and sunk a new shaft, on the north side of the zone of lode-indicators, this time meeting with encouragement by finding small masses of ore at intervals until the great body of solid pyrite was disclosed. After some further exploration it was thrown into an open-cast mine, following the example of the Rio Tinto. It has today a million tons of ore developed, and half as much in the cementation yards in process of leaching.

A matter of peculiar geologic interest is disclosed at the Herrerias, which may have a bearing upon the genesis of these pyritic deposits in general. Toward the east end of the property is a cross-cut 20 ft. deep, serving as an exploratory trench across the faintly indicated lode. It begins, on the north side, in a dark close-grained igneous rock, consisting mainly of labradorite and pyroxene, that would be classed in the field as an andesite. Proceeding southward this soon alters to a greenish granular rock, exhibiting the characteristics of

the so-called 'porphyry' at Rio Tinto. This continues for 20 ft., and is succeeded by a pale yellowish rock, also fine-grained and noticeably porous, with faint iron-oxide staining in the open spaces. Following this, southward, is a mass of highly ferruginous material, with abundant iron hydroxide. Much of it would apparently contain no less than 30 to 40% of metallic iron. In the altered portions of this dike is much sericite, and it is conspicuous that the slates on the south side of the lode are usually converted into sericite schist to a distance of three to six feet. I observed the same phenomena in the lower levels of the San Dionysio mine at Rio Tinto.

As another fact of observation, I may record that in the Herrerias mine the cross-cuts driven into the slate reveal seams of quartz and also of calcite, the latter often occurring in parallel veinlets, close to the orebody, but the superintendent, Alphonse Perbas, informed me that calcite has never appeared in the ore itself, although quartz masses are not infrequent. The slates, furthermore, have lost much of their slaty character near the lode, and outside of the sericitized zone they generally, according to my observation, present a granular facies for some distance.

Another interesting feature was the existence of belts of purple slate, very hard and lustrous, and extremely fissile, which slate is said to contain from 5 to 15% of manganese di-oxide. The statement was made to me by Mr. Perbas that this manganiferous slate is one of the most dependable indications of the existence of cupriferous pyrite orebodies in this district, and that he has observed it over large parts of the pyrite area in Huelva, and also in Portugal.

The Herrerias orebody is 98.5 ft. wide at a depth of 295 ft. from the surface. Above this it splits into two portions, one of which terminates abruptly at a depth of about 140 ft., while the other (the north branch) narrows upward, and then divides into three stringers, which develop slight enlargements at intervals. At the Rio Tinto the size of orebody is also variable, but is seldom narrower than 60 ft., and in the San Dionysio it attains a width of more than 200 feet.

Antonio Carbonell, in a private report, distinguishes between the various surficial indications of the Huelva pyritic orebodies, as follows: (1) Those which have been so completely eroded as to leave only a remnant of iron oxide, simulating a gossan or iron-hat. (2) Those in which a well-defined gossan has been formed directly in contact with the ore. (3) Those in which the iron-bearing solutions had penetrated through the slate above the orebody, giving indications of the existence of a deeply buried deposit. (4) Those in which no evidence is seen on the surface, and which have been discovered accidentally by excavations for other purposes, or by work done on the basis of purely geologic reasoning. He cites the orebodies in the Cabezas Rubias district as examples of the third class, and to this also pertain the Herrerias and Cabeza del Pasto farther west. Throughout the entire pyrite zone similar conditions are found, and, apart from

those that have been explored, the number of indicated deposits is enormous.

Inspection of the map of the province of Huelva will afford an impression of the wide distribution of these pyritic deposits through the zone of parallel basic intrusives. It will be seen that the Rio Tinto and the Peña del Hierro lie at the extreme eastern end of the belt in Huelva; that Tharsis is just west of the centre; and that a well developed area, from south to north across the zone, is found in the central portion. As Antonio Carbonell has pointed out, this development has followed, and has not preceded, the construction of railroad facilities. The recent developments at the Lagunazo, Herrerias, and Cabeza del Pasto, and the reported development of high-grade copper-bearing pyrite in the San Venancia mine, seven miles from the river Guadiana on the Portuguese frontier, led to the belief that the western area of the field may become highly important. It is also noteworthy that the northern edge of the ore-zone is still characterized by a line of thermal springs carrying iron in solution, and by one yielding sulphuretted waters.

The character of the ores throughout the zone is so similar that only an expert could distinguish between them, and it would often puzzle one to tell the difference between ore from the Tharsis and that from Rio Tinto. It is all pale yellowish-gray in color, with sometimes a greenish cast; it is lustrous on a fresh fracture, but dull on the fracture-planes. It breaks into sharply angular pieces, usually tending toward the form of a parallelepiped. It is never seen in crystal shapes, but would be described as a highly fissured massive one. It is not simple pyrite (FeS_2) but is an intimate mixture of the di- and mono-sulphide of iron ($x\text{FeS}_2 + y\text{FeS}$). In rare cases copper sulphide also enters into the mixture, and the ore then acquires a yellow color from chalcopyrite. This type is more abundant in the San Dionysio mine than in any other that I have seen, but I am told that the ores in the Cabezas Rubias district show the same characteristic, and considerable chalcopyrite is reported also from the San Venancia.

The copper for the most part follows the parting-planes in the pyritic masses, and consists of a coating of chalcocite, mostly of the sooty variety, and films of chalcopyrite. This physical occurrence may explain the facility with which the copper can be leached out. One constantly hears the opinion expressed that the copper is chiefly secondary and that the deeply buried deposits will prove lower in that element. This is a matter of vital importance for the future of the pyrite zone. Its ability to hold its own in the pyrite market of the world depends almost wholly upon the copper content of the ores.

The theory that the deeply buried masses of ore are low in copper would seem not to be borne out by the exploratory work done at Herrerias* and Cabeza del Pasto, where the ore was first found at depths of 140 to 200 ft.

*This does not imply that the copper content will not be low at profound depths.

below the surface and the copper content proved to be above 3%. At the San Venancia, on the other hand, the ore (four metres of solid pyrite and ten metres of mixed pyrite) contained only about 0.3% copper. At La Rica Ines, in the Cabezas Rubias district, where obscure indications were followed down to a body of rich pyrite, the copper content varied from 0.8 to 4% with an average of nearly 47% sulphur.

It is customary among the operators in the Huelva pyrite field to assume that the primary ore contained from 0.3 to 0.6% copper.† The general average of 2% is attributed to secondary enrichment. At the Rio Tinto about three-fourths of the copper present is secondary, persisting to the lowest level of the San Dionysio (the 32nd), over 1200 ft. below the surface. The Rio Tinto yields the normal average of 2% from the bottom of the great open-cut, 590 ft. below the former surface, and 1150 ft. on the incline of the vein from the original outcrop. It is not uncommon to find zones, which possess a distinctly bluish-black hue from chalcocite, that are very much richer. Sometimes considerable quantities are mined that assay as high as 10 to 11% copper.

History of the Huelva District

By D. W. Brunton

The discovery of mineral in this district occurred at such an early period in this world's history that no trace of the date is now obtainable. History shows that the Phœnicians occupied the southern portion of Spain at least 240 years before the building of Solomon's temple, or 1240 B.C. The enormous amount of brass consumed in the building of the temple was undoubtedly made from copper mined in what is now known as the Huelva district.

The exact date of the Phœnician occupation cannot now be fixed, but the extent of their operations is attested by the numerous workings and the immense piles of slag. Unlike the Roman workings of later date, the Phœnician dumps and slag-piles never contained coin, and as coinage of money was invented about 700 B.C. it is evident that the Phœnicians must have been driven from the mines at or before that time, but by whom it is impossible to state. Not only is there sufficient evidence to show that the bronze for Solomon's temple was produced in this district, but it is evident that the miners of the district knew the destination of their product, as a round hill on the Rio Tinto river, a prominent mountain separating the north and south lodes of the Rio Tinto mine, and a village about four miles from the mines were all named after King Solomon. These names have not been given in recent times, for in the 'Rua Figueroa', written in 1557, the village in question is referred to as Zalamea la Vieja, or the Ancient Town of Solomon.

The Carthaginians invaded Spain in 237 B.C., and were in turn driven out by the Romans 32 years later. The date of Roman occupation can be fixed by the Roman coins found frequently in the slag-heaps, and in both surface and underground workings. These range through

the reigns of Augustus, Claudius, Nero, Vespasian, Trajan, the Antonines, Gallienus, Aurelian, Constantine, Grotian, Theodosius, down to Honorius. The remains of ancient villages with streets of dressed stone, pottery, and glassware are common on the surface, while in the old mine-workings are found picks, hammers, water-wheels, and ropes.

In the southern lode of the Rio Tinto in 1772 a copper plate, three feet by two feet by $\frac{1}{8}$ inch thick, was found fixed to the side of a drainage-level containing an inscription showing that it had been placed there during the reign of the Emperor Nerva, A.D. 97.

Roman operations at the mines must have terminated when the Vandals, Alans, and Suevi overran Spain A.D. 409, and after this for more than a thousand years no record exists that mentions the operation of these mines.

In 1556, Philip II delegated a priest named Delgado to examine the mines of Zalamea la Vieja. His report made on August 15 of that year, gives a pretty accurate description of the Rio Tinto mines.

About the middle of the 17th century a concession was granted to Alvaro Alonzo, allowing him to utilize the waters flowing from the mines in such a way "that iron placed in them may be converted into copper".

In June, 1725, Liebert Wolters, a Swede, obtained a lease for 30 years from the King of Spain and took possession of the Rio Tinto mines.

In 1742 an English woman named Mary Herbert obtained a warrant placing her in possession of the Rio Tinto for an indebtedness.

In 1746 the mines had passed into the possession of a nephew of Wolters named Tiquet, who obtained a lease for 30 years from that date, and it is believed that under his management the first active working of the pyritic ores recommenced after an idleness of nearly thirteen centuries. After the expiration of Tiquet's lease the mines were worked by the Government more or less irregularly until 1829, when the property was again leased to private operators.

In 1873 the mines were sold outright by the Government to the present Rio Tinto Company.

WHEN an explosion occurs in a large mine, with probable loss of life, an immediate start should be made toward the re-establishment of ventilation; assistance should be summoned from adjoining mining companies, from the State mine inspectors, and from the nearest U. S. Bureau of Mines car or safety station; and a working force with supplies and plans should be organized early. The saving of men after an explosion or mine-fire is the first consideration, and their location in the mine is of first importance. If men have come out of the mine after an explosion, there is a probability that other living men may be in adjoining workings. There is usually some one, an engineer, a superintendent, night foreman, or fire-boss, who has a good idea of where the men were working, even if the entire day shift is imprisoned in the mine. A well considered plan of action is better than hasty though well meaning effort.

Storage of Coal

*The spontaneous combustion of coal lies at the bottom of the subject of storage. Every engineer is familiar with the phenomena of self-heating of coal. For all that, the phenomenon is a relatively rare one. If we counted the times a portion of coal was stored where it would be undisturbed for a few weeks, the number of such storage operations in any one year would mount into the millions. Of these, a relatively small number show the phenomena of spontaneous combustion. There is no spontaneous combustion of anthracite coal, and very rarely does the domestic consumer of bituminous coal find troublesome heating. The main interest in the subject lies in the large piles needed for reserve for public-service utilities and the industries.

The heating of coal is believed to be a surface phenomena. If a ton of bituminous coal could be delivered in a single cube, each dimension would be about 2.8 ft. If the coal heats, it is due to something that goes on with respect to the surface and not something that happens inside of the piece. So far as we know, this is true no matter how small the piece is divided. If this cube, having originally about 47 sq. ft. area, is reduced to something about 16-mesh screen, there is an acre of exposed coal surface. It is perfectly obvious from this why it is that trouble from spontaneous combustion originates in fine coal, because the great increase in extent of surface does not begin until we get below $1\frac{1}{2}$ nut. If fine coal is kept out of the pile the heating surface is so relatively small as to remove the cause of spontaneous combustion.

A unit of area of this coal surface generates a certain amount of heat, provided it can find combining material. The amount of heat generated depends upon the temperature of the piece of coal. That is to say, coal put into storage at a temperature of 80° will generate very much more heat per unit of surface than if put into storage at the temperature of 60° . I cannot say just how much more, but the chemists tell us that in general the rate of chemical reactions doubles for every 10° rise in temperature, and if that applies in this case, 20° higher in temperature means a four-fold increase in the amount of heat generated. It has already been a matter of observation that coal stored during the hot months of summer and in heated areas is much more liable to spontaneous combustion than coal stored in colder climes and in cooler portions of the year.

Another most important factor is the freshness of the broken surface. A freshly broken surface of coal has a rate of heat generation that is a function of the kind of coal. It is practically zero with anthracite and is largest with the younger coals. The quantity of oxygen contained in the coal seems to be the fairest measure of this rate, although by no means reliable. The high oxygen coals of the Middle West and the sub-bituminous coals and lignites of the West show increasingly active rates of heating. The coal surface apparently becomes satis-

fied in time, and the heat produced falls to practically zero. This means that for the first few days or weeks a freshly broken surface is very much more active than after a few weeks or months. Fires rarely occur after surfaces have been exposed for three months.

Since the rate of heating increases with the temperature, it is evident that if the heat generated is not removed, the process becomes a self-aggravating one, in which case the rate of heat generation instead of falling may rise with time. If the temperature of the pile reaches 140° or 150° and continues to rise, there is a very considerable probability that, within a few days or a few weeks, a destructive temperature will be reached. If the temperature reaches 160° or 180° , there is almost a certainty that a destructive temperature will be reached and the coal must be moved. Immediately the question of getting rid of the heat is presented.

Suppose that coal was delivered in four uniform sizes and put in a conical pile by dropping at a single point. The granular arrangement of parts would be such as to furnish a foundation over nearly the whole pile, of larger sized pieces, and the lower flanks of the pile would be of the larger sizes. Nearly all of the smallest pieces would be in the central core of the pile. In the region of large pieces air would move freely and the coal surface exposed would be a minimum; hence there would be little likelihood of heating. In the centre of the pile the movement of air would be small, while the amount of heating surface would be great. If the fine coal is so densely packed as to prevent an exchange of air, there will be no heating because there will be no supply of oxygen to combine with the active surfaces. Somewhere between the two extremes of the central core of fine coal and the large-piece region, there may be areas where the ventilating current is just sufficient to supply oxygen for a maximum rise in temperature and insufficient to remove the heat as generated.

We know that if coal can be sealed tight, as in a glass jar, the oxygen soon disappears and the coal cannot continue to heat because of lack of oxygen. With no ventilation there will be no rise in temperature, and the zero point will represent the condition of coal sealed from the air or so densely packed that air cannot circulate. If, on the other hand, there is sufficient ventilation, the heat is all carried away as fast as generated. At some point between these two extremes there may be a condition of ventilation which will supply just oxygen enough to provide for a maximum rise in temperature. Since we have no means of knowing just what the ventilation is in any given portion of a pile, there is great hesitancy in advocating ventilating schemes for coal piles, as we are as likely to make trouble as to prevent it unless extreme and uniform ventilation is assured.

There are many more minor factors. One of the troubles has been that undue attention has often been given to minor factors, such as sulphur, height of pile, volatile matter, etc., while main factors, such as initial temperature, breakage in handling, freshness of coal, and coal screening before storage, have been overlooked.

*Abstracted from an address by O. P. Hood of the U. S. Bureau of Mines.

The R & S Molybdenum Mine

*The R & S molybdenum mine is situated in the western part of the Culebra range in Toas county, New Mexico. It lies about 27 miles from Jarosa, Colorado, on the San Luis Southern railway. The mine lies at an elevation of about 8700 ft. above the sea-level.

The yellow molybdic ochre that formed as an alteration product at the outcrop of the veins was long regarded as sulphur and gave the name to the gulch on which the mine is situated. About the time of the entry of the United States into the War it was realized that the black substance associated with the 'sulphur' was not 'graphite' but molybdenite, and the Western Molybdenum Co., of La Jara, Colorado, was organized to develop the prospect. No systematic development work was done by this company and no ore was produced. In November 1918 the R & S Molybdenum Co., of Denver, was formed and took over seven claims from the Western Molybdenum Co. and the new company has filed additional claims to increase the total holdings to about 300 acres. Development work was done throughout the winter, production began in the spring and was continuing at the time of our visit in the fall of 1919.

The buildings at the mine were an office, bunk-house, ore-sorting shed, and a blacksmith shop. The company has built a mile of good road to connect the mine with the main road on Red river. A remodeled gold-mill operated by water-power, situated five miles from the mine, is being used at the present time, involving a haul of ore by auto-truck. The equipment at the mill consists of a jaw-crusher, ball-mill, classifier, and flotation plant.

A tunnel has been driven for 300 ft. along one of the southernmost of the group of veins exposed on the property, and in places this has been stoped to a height of 60 ft. Only enough ore has been withdrawn to allow the work to proceed and considerable broken ore was still in the mine in September. The ore as it comes from the stopes is said to average about 2% MoS₂. This material is run over the grizzly and the fine goes directly to the ore-bins. The coarse material is hand-sorted and the tenor of the ore is raised to about 4%. Concentrate runs from 80 to 91% MoS₂ and no trouble is experienced in producing 90% concentrate. The concentrate is said to be low in copper and phosphorus.

The rocks of the region are a soda-potash alaskite porphyry in which the ore occurs, a dark gray granodiorite porphyry, and volcanic tuffs and flows.

The alaskite has been sheeted for about a thousand feet in a north-south direction along Sulphur gulch and this sheeting is said to extend for several thousand feet in an east-west direction. There are a number of main fractures which are approximately parallel and strike about N. 79° W. The veins are all the result of mineralization along these fracture and shear-zones. The larger ones follow the main shear-zones, but smaller veins and flats branch, intersect, and re-unite forming a complex net-

work. Yellow molybdic ochre makes the outcrop of the veins conspicuous and easily traced. Development work has been confined almost entirely to one vein near the southern border of the group, but its surface indications were no more promising than those of several other veins. In the 300-ft. adit the mineralized zone has been rather constant in its characteristics, varying in width from 4 to 6 ft. The ore-zone is shattered and sheeted alaskite with the ore filling the fracture. Small veins and films of ore penetrate the wall-rock, but there is almost no replacement of the alaskite and so very little molybdenite is found disseminated in it.

The mineralized zone which is being stoped contains a comparatively small proportion of vein-filling, as sericitized alaskite lies between the small branching veins. This vein-filling is made up mostly of quartz with a large proportion of molybdenite, some pyrite, a little chalcopryrite, fluorite, sericite, apatite, biotite, chlorite, and calcite. The relationships show that the alaskite was thoroughly sheeted before the introduction of the vein minerals, but that minor movements continued up to the time of the deposition of calcite, the last mineral to form.

Molybdenite is generally regarded as a primary mineral deposited by magmatic waters, but it has been described from deposits that have been formed at vastly different depths and at very different temperatures. In the R & S mine its association with pyrite, fluorite, sericite, biotite, and quartz in a mineralized shear-zone indicates that the ore has been formed by ascending magmatic waters, probably at a moderate temperature.

As yet molybdenum ore has been found in only a comparatively small area in Sulphur gulch. The veins are in a zone of shearing in an alaskite and there appears to be a number of veins that promise to be of sufficient width for economical mining, and many smaller stringers. The veins are of a kind that not uncommonly lack persistence and it is not safe to assume a continuation of the ore-bodies much beyond the developed areas. However, the 300-ft. adit exposes several thousand tons of ore.

THE Bureau of the Mint, with the co-operation of the U. S. Geological Survey, has issued the following statement of the preliminary compilation of the production of gold and silver in the United States during the calendar year 1920. Compared with the production in 1919 these figures indicate a decrease in the gold output of \$10,824,000 and in the silver output of 117,941 ounces.

State	Gold. oz.	Value	Silver, oz.	Value
Alaska	380,034	\$7,856,000	792,761	\$804,745
Arizona	239,118	4,943,000	6,098,251	6,190,518
California	692,019	14,305,300	1,513,495	1,536,394
Colorado	368,298	7,613,400	5,572,407	5,656,718
Idaho	22,509	465,300	7,531,253	7,645,201
Michigan	510,601	518,329
Missouri	19	400	123,219	125,083
Montana	88,971	1,839,200	13,583,164	13,788,677

*Abstract of an article by E. S. Larsen and C. S. Ross, of the U. S. G. S.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

UNITED EASTERN DECLARES DIVIDEND.

KINGMAN.—The Dardenelles mine has shipped its seventh carload of ore. Shipments are yielding approximately \$1200 net per car. This ore production is coming from the 160-ft. level. The Dardenelles mine is situated in the Chloride district near the old Elkhart mine.

Judge Bollinger has handed down a decision favoring the plaintiff in the matter of the shareholders of the Midway Mining & Milling Co. v. the Midway Moss Mining Co. This decision voids the action of the directors of the old company in transferring the title of the property to the new organization, the Midway Moss Mining Co., and compels the re-transfer of the holdings and the dissolution of the new company.

Frank A. Garbutt has petitioned the Superior Court for a new trial in the cause of Frank A. Garbutt against the Schuylkill Mining Co. and C. A. Burke in which a receiver was appointed by Judge Crosby for the Schuylkill Mining Co. The cause of the original litigation grew out of the various loans made by Mr. Garbutt to the Schuylkill Mining Co. aggregating \$300,000. The company secured Mr. Garbutt by a mortgage on the property. Mr. Garbutt sought to foreclose this mortgage. The defendants raised the issues that they were prepared to finance the company and the judgment gave them time to come in, build a mill, and develop the mine under a receivership, while at the same time the interests of Mr. Garbutt were to be conserved. The mines at issue are the Tennessee and Schuylkill at Chloride. It is alleged that the Tennessee has about 30,000 tons of good ore opened with the possibility of opening 70,000 tons or more with further work.

OATMAN.—The drift on the 400-ft. level of the Telluride mine is reported to have opened ore that averages \$30 per ton in gold. This ore-shoot, which was first opened on the 500-ft. level, assayed \$40 per ton. The property of the Telluride company corners on the Tom Reed and the United American properties.

The United Eastern Mining Co.'s directors at a recent meeting held in Los Angeles declared the regular quarterly dividend of 15c. per share payable January 28 to stock of record January 8. The company paid 72c. per share in 1920. The total dividends to date have been \$3,339,350. It is reported that the cash reserves of the company are in excess of \$900,000. Approximately 102,000 tons of ore was treated in 1920 which assayed better than \$21 per ton.

COLORADO

MINING AT CRIPPLE CREEK IS ACTIVE.

ASPEN.—The recent discovery in the Jenny Lind tunnel by the Park Tunnel Mining Co. has brought about renewed activity in the Tourtelotte Park section. Lessees have filed applications for leases on properties traversed by the tunnel, now controlled by the Tunnel company. The Jenny Lind find on Sam Houston ground is reported holding up in value and in strength of the vein.

CRIPPLE CREEK.—A surplus of labor, the first in four years, is reported at the mines, where notices 'No Miners Wanted' are posted. Wages have been cut 50c. per day, affecting all employees. The second diamond-drill test in the east end of the district is reported progressing with depth attained of beyond 800 ft. Two phonolite dikes with some mineralization have been passed through and the drill is nearing the Bolivia Dike junction, the objective point. Shipments continue steadily from the Portland, Cresson, Vindicator, Modoc, and Granite companies properties, from operations on company account; and, in addition, renewed activity among lessees is reported.

RICO.—Operations are to be resumed at the Emma mine at Dunton, owned by A. E. Reynolds of Denver. A contact has been proved between the fifth and sixth levels and a raise is to be carried up from the sixth to prospect this contact, believed to carry high-grade ore. The shaft is now being unwatered by a force in charge of J. Clamp, mine superintendent. Ore running high in silver has been struck on the J. W. Burns property on the west side of the river at Burns near Rice. Water is causing trouble and a Cameron sinker will be brought up and placed in the winze where the discovery was made. The property is operated by lessees. Ore of shipping grade is being saved for shipment on the Badger group of claims in Allyn gulch, operated by Hay Brothers of Rico.

MICHIGAN

COAL-PULVERIZING PLANT FOR MICHIGAN SMELTER.

HOUGHTON.—No copper is being shipped out of the district. Metal is accumulating at all smelters. Mohawk and Wolverine are the only mines that have small metal stocks, Calumet & Hecla, Copper Range, and Quincy have been unable to make any reduction of their surpluses. Calumet & Hecla, which formerly had a market for oxide copper, is shipping none of that now. The

greater portion of it, which comes from the leaching-plant, is being smelted. Fourteen furnaces are still in commission at the smelters, eight being closed. Two of the fourteen in use are of the large type, of 1,000,000 lb. monthly capacity. Twelve are of the smaller type, each having a capacity of 40,000 to 50,000 lb. per charge. None of the furnaces is being pushed to capacity.

Calumet & Hecla sold \$300,000 worth of silver in 1919, but the annual report for 1920 operations will show the income from silver considerably reduced. Silver dropped in price during 1920 and less of it was sold by the company. None has been shipped in recent weeks. The production of silver also will show a falling off during the period of curtailed operations.

Equipment has been ordered for the new coal-pulverizing plant at the Michigan smelter, as an auxiliary for coal-dust burners at the furnaces. It is expected the plant will go into operation in the spring. Coal now is fed into the furnaces automatically as it comes from the coal pits. When the pulverizing plant is in use the coal will be ground and sprayed into the furnace as fuel-oil would be sprayed. The entire operation will be automatic, the pulverized coal being forced through pipes and into the furnaces by air pressure. The method will be new in the Copper region.

Franklin, which has been shut-down since June 1 last, but which has been keeping its shafts free of water, is now preparing to cease even pumping operations. The pumps and other underground equipment that can be moved will be brought to surface and the shafts permitted to fill with water. The water from No. 2 flows into No. 1 and all pumping has been centred in No. 1. The fires will be drawn in the boilers in a few days and the property closed entirely for an indefinite period. Franklin stopped production in May 1919, but from that time until the first of June 1920 it did considerable development work. It was during the course of these development operations that well mineralized ground was entered on the 39th or bottom level. The shaft was sunk from the 37th to the 39th and it is the belief that the rich streak in the 39th extends upward for ten levels. If subsequent developments prove this to be true, it will give the company a large tract of good ground.

NEVADA

CONSOLIDATED VIRGINIA COMPANY TO BE REORGANIZED.

ELY.—R. C. Gemmell, general manager for the Utah Copper company and assistant managing director of the Nevada Consolidated, and D. D. Moffat, consulting engineer for the Jackling interests, recently inspected the Nevada Consolidated mines and reduction plant and then left for San Francisco, where they were to confer with D. C. Jackling regarding plans for the future for the Utah Copper, Nevada Consolidated, and Nevada Northern railroad.

VIRGINIA CITY.—The United Comstock is employing 125 men at Gold Hill and when work is started on the tunnel from the Knickerbocker, Jacket, Belcher, and Imperial shafts, in addition to that now being done from

the portal, this force will be increased greatly. The tunnel is being driven at a rate of 300 ft. per month. The Consolidated Virginia is to be reorganized, according to action taken at the recent annual meeting of the company in San Francisco. The capital stock is to be increased from 216,000 to 2,160,000 shares of a par value of \$1 each and the exchange is to be 10 for 1. The annual report of Axel Wise, superintendent, shows that the company mined last year 17,706 tons of ore of a gross value of \$353,960 and a net value of \$259,686. A total of 3275 ft. of development work was done. The superintendent says: "The east vein is a pre-mineral vein and at its intersection with the Comstock lode it formed a large and rich bonanza. The east vein was and is rich and productive, but it does not carry the enormous tonnage that the Comstock ledge does. In mining the Comstock lode and the east vein, selective mining was carried on and the fills of low-grade material were left. The present scheme is to put the mine in shape to handle this low-grade material at a small cost. This can be done by perfecting the haulage-ways and blocking out large sections of the fills in such manner that they can be worked on a large scale and at low cost. By judiciously mixing lower-level ore with the large tonnage of upper-level ore we can keep the Mexican mill running to capacity for an indefinite time. Our aim is to mine and mill 4500 tons every month in the Mexican mill at a cost of \$27,000 per month, with a mining and milling cost of \$6 per ton."

MINA.—The 150-ton flotation plant of the Simon Silver-Lead is said to be half finished. It is announced that the company, instead of getting power from semi-Diesel engines, will obtain electric power over a line from Millers, the construction of which would cost \$60,000.

ARROWHEAD.—Ore five feet wide, with one to two feet assaying as high as \$1000 per ton in silver and gold and the remaining three to four feet assaying \$30 to \$40, has been opened in the 50-ft. west drift on the third, or 267-ft., level of the Arrowhead. The 45-ft. east drift on this level also is in the ore-shoot opened on the upper levels, proving it to a depth of 300 ft. on the dip of the vein. The shaft is 320 ft. deep and it is 20 or 30 ft. below water-level. New equipment consisting of a 25-hp. hoist and a steel head-frame is now in use. Air-drills are not used, because drilling by hand has been found more economical and equally as efficient.

DIVIDE.—The shaft of the re-organized Belcher is to be sunk from the 350-ft. level to the 500 or 550-ft. point, according to N. M. McCormick, manager. Recent work has been confined to the 350-ft. level, where seams of low-grade ore have been found. A cross-cut from the southeast drift on the 800-ft. level of the Tonopah Divide has proved that the rich ore recently opened at that depth is only slightly wider than the drift. Cross-cuts are being driven on the 1000-ft. level in prospecting for the extension of the shoot on the 800-ft. level. A drift being driven toward the Brougner on the first level has been in \$30 ore for 65 feet.

WEST DIVIDE.—Edward Bevis, of Tonopah, has succeeded L. L. Patrick as manager of the West Divide, and

John Bricker has succeeded George Pearson as superintendent. Bertha Garnett of Goldfield has resigned as secretary and the affairs of the company are now handled in the office of Allan Rives at Tonopah. Heretofore the company has been operated partly from Goldfield and partly from Tonopah and the change is said to be for the purpose of securing more economical operation by making Tonopah the headquarters.

UTAH

PLAN TO SHIP BULLION TO NEW YORK BY WAY OF SAN FRANCISCO AND THE PANAMA CANAL IS DELAYED.

SALT LAKE CITY.—During 1920, the number of fatal accidents in the metal mines of the State totaled 20. In addition, six miners lost their lives in snow-slides at Alta; but these accidents cannot be charged to mining operations. During 1919, the total number of deaths was 15, the lowest in years. During 1920, fewer men were killed by falling rock, but there was a large increase in the number killed by explosives. The Industrial Commission reports that 30% of the accidents in 1920 could have been avoided by the companies; 40% of the total was due to carelessness of fellow employees; 10% to carelessness of victims; while the remaining 20% was purely accidental. In the smelters of the State, three men were killed, as compared with four in 1919; while in concentrating plants, three were killed, as compared with one in 1919.

The annual meeting of the Utah Chapter of the American Association of Engineers was held on January 11. Officers elected for the following year are C. C. Burt, president; T. S. Bult, vice-president; W. H. Carrick, secretary; J. Blickensderfer, C. S. Fisher, and C. J. Ulrich, directors. The Chapter will make an effort to secure the 1922 convention of the national association for this city.

The plan of local smelting companies to ship bullion to San Francisco and then by boat to the Atlantic seaboard, has been temporarily halted, owing to the order of the Interstate Commerce Commission suspending the rate of \$6.50 per ton on smelter products from this city to San Francisco. At the present time, the rate of blister copper from the Garfield smelter to the Baltimore refinery is \$22 per ton and to the Perth Amboy refinery \$21.40 per ton. It had been planned to ship the blister copper by way of San Francisco and the Panama Canal, and the total transportation charge, including insurance, handling, etc., would be between \$15 and \$16 per ton, effecting a saving of \$6 to \$7 per ton in freight charges. A hearing on the question to determine whether the \$6.50 rate, or a higher rate, should apply will take place in this city on February 16. At the present time, the Garfield smelter is shipping a small quantity of its blister copper to the Tacoma refinery.

PARK CITY.—Arguments under the writ of certiorari granted the Silver King Coalition Mines Co. on its appeal from the judgment in favor of the Conkling Mining Co. for approximately \$500,000, are being heard by the United States Supreme Court. The case has been one of

the most bitterly contested mining litigations in the West. The Conkling company sued the Coalition for the wrongful extraction of ore from the Conkling claim, owned jointly by the two companies. The Coalition company set up the claim of extra-lateral rights in defence and prior ownership of part of the property in dispute. In the United States District Court for Utah, Judge J. A. Marshall on July 15, 1912, decided in favor of the Coalition company on both defences. The Conkling company appealed to the Eighth Circuit Court of Appeals, where the decision of Judge Marshall was reversed on February 12, 1916, and judgment entered in favor of the Conkling company for \$383,000. The Coalition company then appealed to the United States Supreme Court. Since the

HYDRAULICKING NEAR ATLÁN, B. C.

commencement of the suit, some of the most prominent people with both companies have died. David Keith, president, and Thomas Kearns, vice-president and general manager of the Coalition; Judge Curtis H. Lindley, one of the attorneys for the Coalition; Nicholas Treweek, president of the Conkling company, and E. B. Critchlow, counsel for the same company, have died.

EUREKA.—Ore shipments from this district for the first week of the new year totaled 181 cars, of which the Tintic Standard shipped 61; Chief Consolidated, 32; Dragon, 23; Iron Blossom, 15; Eagle & Blue Bell, 13; Iron King, 10; Victoria, 9; Colorado, 4; Swansea, 4; Mammoth, 3; Bullion Beck, 2; Centennial-Eureka, 2; Gold Chain, 1; Sunbeam, 1; Gemini, 1.

BRITISH COLUMBIA

CANADIAN PACIFIC COMPANY ESTABLISHES FREIGHT-RATES BASED ON THE VALUE OF THE ORE.

PRINCE RUPERT.—H. S. Munroe, general manager for the Granby Consolidated M. S. & P. Co., passed through here on his way to New York. He denied emphatically that any negotiations were pending between either the C. P. R. or the Consolidated M. & S. Co. for the purchase of the Granby company's holdings in British Columbia,

and he further denied that any of the Trail engineers had made an examination of the Anyox properties. Mr. Munroe said a satisfactory wage-adjustment had been made, that the plant was working smoothly and turning out more copper than it had done for some time. The Premier mine has started to ship ore to tide-water; two Holt tractors are being used over part of the distance. The Bellevue group, on the Illianee river, is developing well. A 40-ft. lode has been traced for nearly a mile, and samples of the openings are said to average 23 oz. in silver and \$1.40 in gold and 3.5% lead. Development work is to be continued throughout the winter, and if the price of silver is satisfactory it is proposed to erect a concentrating plant next summer.

It appears that the closing of the Dolly Varden mine was not due to labor trouble, as was at first thought, but that the owners considered that indications pointed to cost of labor being cheaper in the spring, and, as there is no possibility of shipping during the winter, it would be more economical to close the mine. Last spring, when labor had the whip hand, it drove a hard bargain with the Taylor company, and it looks rather as though the present move was in the nature of retaliation. Anyhow, it will not tend toward a better understanding of capital and labor in the district.

NELSON.—Several of the mines in the Slocan, including the Silversmith and the Whitewater, have been shipping recently to the United States S. & R. Co.'s smelter, at Midvale, where, it is claimed, a better rate is obtainable than at Trail. This traffic, however, has received an abrupt check by a change in the C. P. R. freight-rates which went into effect on December 23. Shippers had been in the habit of declaring the value of their consignments at the minimum, namely \$50 per ton; the understanding being that in the event of loss in transit the railway company was responsible only for the declared value. By the new schedule the freight-rate is to be based on the actual value of the ore, as shown by the smelter return, and, as little ore worth less than \$150 per ton is sent out of the Slocan, the new rate will mean an increase of more than 50% to the shippers. The bulk of the ore cannot stand this new rate, and shippers are looking upon it as practically amounting to a mandate on the part of the C. P. R. that all ore must be smelted at Trail. This coming at a time when Trail is offering only warehouse receipts, redeemable when the metal is marketed, for ores received is causing much bitter feeling among the operators of the small mines.

ONTARIO

NIPISSING PAYS \$600,000 IN DIVIDENDS.

COBALT.—As the result of power shortage, coupled with the low price of silver, only about ten of the silver mines are now being operated out of 19 which were working during the summer, and most of these are producing on a much reduced scale. Ore shipments last week were light, amounting to only 162,484 lb.; no bullion was sent forward. The number of men at work in the camp is

estimated at about 1000, as compared with 2000 employed during the summer. While it is believed that the present supply of power can be continued until well on in February, the situation is uncertain, being dependent upon the weather. The Nipissing is the only company which has not considerably curtailed its operations during recent months.

On February 15 wages to the employees of the mining companies of the Cobalt district will be reduced 75c. per day or approximately 15%. A statement by the Temiskaming Mine Managers Association sets forth that owing to the price of silver being half what it was a year ago about 18 properties had been compelled to close down entirely or suspend operations, while those companies still maintaining their output have reduced their working forces. The Nipissing disbursed a dividend and bonus aggregating 10%, amounting to \$600,000, on January 20.

The surface veins found on the Kerr Lake prove disappointing with underground work. A raise on one of them to within 30 ft. of the surface has not disclosed any silver content and enrichment appears only to extend downward for a few feet. The Kerr Lake is negotiating with the Hargraves Consolidated with a view to obtaining a working option on two properties adjacent to its own.

The La Rose is obtaining a good grade of ore from its University and Princess properties—work on the original La Rose being practically confined to the powder-house vein from which several thousand tons of broken ore in stopes are being hoisted.

KIRKLAND LAKE.—This camp has benefited by the slackening of operations at Cobalt, as many of the skilled men recently employed at the silver mines have been taken on at Kirkland Lake. The Ontario-Kirkland announces that it has over two years supply of ore for the mill in sight. The shaft has been sunk to a depth of 470 ft. with levels at 100, 300, and 450 ft. and over 2500 ft. of lateral work has been done on the two lower levels opening up a large body of good milling ore assaying from \$8 to \$28 per ton. The company will bring in supplies and machinery during the winter and push construction work on the mill in the spring.

A shipment of gold bullion valued approximately at \$30,000, the output during the month of December has been made from the Kirkland Lake mine.

At the Lake Shore the shaft has reached the 600-ft. level and sinking has been stopped until a level is established and cross-cuts run to tap No. 1 and No. 2 veins. The latter, which underlies Kirkland Lake, is a highly important orebody.

PORCUPINE.—It is anticipated that the Dome Mines will be able to treat an average of about 500 tons of ore daily on its present power supply throughout the winter. It is understood that the present dividend rate of 2½% quarterly will be maintained regardless of the temporary reduction of output, as it is expected that as soon as adequate supplies of power are available the volume of ore handled will be greater than ever before.

COPPER PRODUCTION

The 'porphyry' copper companies as a group produced more copper in 1920 than in 1919, seven companies listed below turning out approximately 422,137,367 lb. last year, against 407,328,114 lb. in 1919, an increase of 14,809,253 lb., or 3.6%. This estimate is based on monthly reports and may later be revised slightly. The actual production of this group of companies in 1918 was 627,832,011 lb., so that last year's output showed a drop of 205,694,644 lb., or 33%.

Utah Copper was the only one of the group that did not turn out more copper in 1920 than in 1919, the decrease being approximately 2,500,000 lb. Utah's production last year was the smallest since 1912, when it amounted to 91,366,337 lb. The record output was 195,837,111 lb. in 1917. Nevada Consolidated's 1920 output gained about 4,328,000 lb. over 1919, but it was 28,308,000 lb., or 24%, under that for 1918. Nevada's record production was 90,735,000 lb. in 1916.

Miami and New Cornelia showed the least curtailment as compared with 1918. The 45,705,000 lb. turned out by Chino last year was 30,930,000 lb. under that for 1918. This company's record production was 79,636,000 lb. in 1917.

The following compares the copper production by seven prominent porphyry companies during each of the past three years, the figures being in pounds:

	1920	1919	1918
Chino	45,705,490	40,488,706	76,635,641
Inspiration	81,250,000	78,036,306	98,540,041
Miami	55,092,288	54,221,638	58,407,563
Nevada	48,299,256	43,871,892	76,607,062
New Cornelia..	40,818,456	39,509,461	46,950,139
Ray	48,397,935	46,011,371	83,599,160
Utah	102,573,942	105,088,740	188,092,405
Total	422,137,367	407,328,144	627,832,011

DECISION IN SUIT OF RICO CONSOLIDATED V.
RICO ARGENTINE

Decision in the apex suit of the Rico Consolidated Mining Co. v. the Rico Argentine Mining Co. for the recovery of ore alleged to have been taken out of the plaintiff's territory has been made in favor of the plaintiff by Judge W. S. Searcy of the Sixth Judicial District Court of Colorado. In his decision Judge Searcy holds that trespass was not willful, but made in good faith. Consequently damages awarded amount to \$29,946.50 against the Rico Argentine company and \$7346.50 against the Marmatite Mining & Milling Co., lessee of the defendant. The judgment of approximately \$37,000 represents the net mine value of nearly 5000 tons of ore extracted by the defendant. Mining men of the district agree that the valuation of the ore contested for in the litigation is small in comparison with the bodies that can be mined by the Rico Consolidated Mining Co. in the light of this new decision. Judge Searcy's decision that the ore-beds, for possession of which the Rico Consolidated Mining Co. instituted suit, were formed by east-west fissures rather than by the Blackhawk fissure reverses theories held among mining men in the past concerning the mineralogy and geology of the

district. As a result of this decision, it is said, claims held by other companies will be affected. Fred Price, president and general manager of the Rico Argentine Mining Co., made the following statement:

"Our counsel contended that the Blackhawk fissure was the source of the enrichment of the beds which we followed into the conflict area. The plaintiff held that the Allegheny and its parallel east-west fissures were the source and apex of the ore-beds. According to our conception of the geology of the district, the Blackhawk is the master fissure. This vein, standing nearly vertical, traverses the country for miles and cuts upon our property a formation which consists of alternate strata of soluble and insoluble lime and sandstone.

"All of the six veins mined upon our property are replacement orebodies in beds of soluble limestone. We hold that these beds were enriched by solutions which proceeded from the Blackhawk fissure that apexes on our ground.

"Two of the fissures, No. 2 and No. 6, have been followed to the Blackhawk fissure, where they merge. At the juncture of No. 6 vein with the Blackhawk ore was stoped out for 100 ft. above the level and into the master fissure. From this one stope Tom Walsh, pioneer mining man of Colorado, took out enough ore to pay for the Camp Bird, the exploitation of which made him the wealthiest operator in Colorado.

"Four of the veins followed into the conflict area outcropped in our territory. As the ore in these beds led into the Rico Consolidated ground over the side-lines, we followed it."

CHILE COPPER COMPANY WILL BUILD REFINERY

Unofficial announcement is made that the Chile Copper Co. is to construct a refining plant at its properties in South America. The Chile company is the lowest-cost producing property in the world. In the third quarter of last year the cost of copper was only 11.179c. per pound, including the selling and delivery expense. The construction of a refinery at the properties would permit a material reduction in this cost, as it would mean that the company could deliver the refined product in this country. The company has the advantage of the low cost of labor—only \$1.25 per day, as well as cheap water-power. Even at the present low price for copper Chile is one of the few companies that can make a profit. During the third quarter of the past year, when practically all the large properties in this country were operating at a loss, the Chile company reported net profit on copper delivered of \$2,105,160, while after all expenses, depreciation, and interest charges were deducted there was a surplus for the third quarter of \$878,008.

AMERICAN ZINC, LEAD & SMELTING CO.

The American Zinc, Lead & Smelting Co. enters the new year with net quick assets of between \$3,500,000 and \$4,000,000, with ore stocks at a minimum and with inventories marked down to the lowest prices. Operations are also down to a minimum and at present it is hard to earn operating expenses. In the first half of last year net earnings amounted to \$344,975; from July on, however, the market for zinc and for all non-ferrous metals, for that mat-

ter, steadily declined, so that the 1920 report will show an operating loss. The physical holdings of American Zinc Co. are today in the best shape in their history. Ore in the Mascot mine is developed for ten years ahead,

RESEARCH GRADUATE ASSISTANTSHIPS

The Engineering Experiment Station of the University of Illinois announces 16 research graduate assistantships for each of which there is an annual stipend of \$600 and freedom from all laboratory fees. Graduates of approved American and foreign universities are eligible for these appointments. Nominations are based upon character, scholastic attainments, and promise of success in the research to which the candidate proposes to devote himself. Some practical engineering experience following graduation is desirable. Additional information may be obtained by addressing the director at Urbana, Illinois.

ARIZONA

Kingman.—F. P. Aylwin and associates have taken over the Dean mine, situated 14 miles from Kingman in the Wallapai mountains. Shipping-ore is being extracted pending the completion of the 75-ton flotation plant. Silver is the chief product, with some lead and zinc. The staff includes Lyman F. Barber, metallurgist, W. B. Dunlap, mine superintendent, Robert Blum, engineer. A new road to the mill is now completed and nearly all machinery is on the ground.

Oatman.—The United Eastern and Tom Reed mines are working close to capacity, general conditions at the two producing mines being favorable. There are plenty of skilled men which tends toward a higher efficiency. The output of both mines for January is expected to be higher than that of December.—The United American is sinking the winze from the lower level at the junction of the vein and the cross-cut.—The Telluride is working a double shift on the fourth and fifth levels. Good ore has been found and drifting is progressing.—The Amalgamated is working one shift cross-cutting on the 600-ft. level, and it is expected to cut the vein about 70 ft. farther ahead.—The Argo is cross-cutting north on the 600-ft. level; so far there is nothing of interest to report in new developments.—The Oatman United is working one shift following a good lead east in hope of picking up the main vein at this depth.

Pima County.—An important development in the mine of the El Tiro Leasing Co. is the opening of an ore-shoot on the 300-ft., or bottom, level. The orebody averages 5% copper and is said to double the ascertained value of the property.

CALIFORNIA

Amador County.—According to Edwin Higgins, manager for the Metals Exploration Co., it will require five months to place the Fremont mine in operating condition. The mine has been unwatered and the 40-stamp mill is being overhauled in preparation for production.—The 40-stamp mill at the Bunker Hill mine near Amador City has resumed operations at maximum capacity. Production was curtailed during the greater part of 1920.

Calaveras County.—J. A. Vigeant is negotiating for control of the Nassau copper mine near Angels Camp. Besides copper, the ore contains some silver and gold.

Nevada County.—The North Star Mines Co. has declared a dividend of three cents per share. This is the first distribution since January 1918. To date \$5,587,000 has been distributed among the stockholders.—Eighty stamps in the Empire mill are in operation. More ore is being mined than at any time since the outbreak of the War.—The Western Precious Metals Co., according to W. A. Simpkins, general manager, will commence the development of a series

of gold veins on the Mitchell ranch east of Grass Valley. No work other than surface trenching has heretofore been undertaken on these claims.

San Francisco.—The annual election of officers for the San Francisco section of the American Institute of Mining and Metallurgical Engineers was held Tuesday evening, January 11. The officers are as follows: Frank L. Sizer, chairman; Edwin Higgins, vice-chairman; C. H. Fry, secretary and treasurer; and James M. Hyde and Lester C. Urem, members of the executive committee. Max Thelen addressed the Section, his subject being 'Impressions of Washington'. Fletcher Hamilton discussed the gold problem and the McFadden bill from the standpoint of the gold producer in California. A number of members expressed their dissatisfaction with the action of the directors of the Institute in New York in levying a 'voluntary assessment' to meet the financial deficit existing at the end of the year. A resolution was finally prepared and unanimously adopted, requesting of the directors further information as to the reasons for the deficit and urging that an investigation of the Institute's publications be made.

Ubehebe.—A carload of lead-silver ore, which is expected to net \$60 per ton, has been shipped from the Arrowhead-Rice property. The ore contains 60% lead and 34 oz. silver per ton. Two carloads of ore are being sacked, but work will be discontinued until a tunnel, which is expected to cut the vein at a depth of 300 ft., has been completed. Three samples, averaging 70% lead, from a width of 8 ft., were obtained from a second vein that is parallel to the first.

COLORADO

Denver.—Thirty-days notices of wage-reductions of 50c per day were filed with the State Industrial Commission by three mining companies late Monday. The Wasatch-Colo-rado Mining Co., of Silver Plume, notified the Commission that "present mining and market conditions force us to take this step to keep from closing the mine and mill". The step referred to was the company's notice of a wage-cut of 50c per day, beginning February 14. The Hollingsworth Mining Co., of Silver Plume, also gave notice of a similar wage reduction. Tomboy Gold Mines Co., Ltd., of Telluride, through N. S. Kelsey, general manager, gave the Commission notice of a 50c cut in wages on February 15.

Telluride.—Ore and concentrate shipments from the Telluride station for December were: Smuggler-Union, 59 cars of concentrate; Tomboy, 48; and the Liberty Bell, 19; total 126 cars. The Belmont-Wagner Mining Co. has engaged John M. Wagner, former manager of the Alta mines, to extend the adit, which was started some months ago, on into the vein. The tunnel is 7 by 7 ft. It will serve the double purpose of securing more ventilation and getting the ore to the mill more easily and cheaply than tramping it. Wagner will select his crew and start work immediately.

IDAHO

Bonnors Ferry.—A 4200-ft. Riblet wire-rope tramway was recently purchased by the Cyanide Gold Mining Co., operating the Buckhorn property, 22 miles north-east of here. This is to be shipped at once to Eileen, 13 miles from the mine and will be installed and ready for use in three or four months. A 50-ton ball-mill has been installed, with provision made for an additional unit of 50 tons. With the tramway in operation the present mill capacity will be 10 tons per day.

Coeur d'Alene.—Work on the new concentrator for the Sunshine Mining Co., operating the Yankee Boy mine on Big creek, is progressing, a large portion of the material for the building now being on the ground. The mill will start with a daily capacity of 50 tons.—The Lookout Mountain Mining Co. has installed a 10 by 10-in. Sullivan compressor on its property in the Pine Creek district and now has

—F. L. Torres, president and general manager of the Eureka-Croesus Mining Co., announced the intention of his company to build a mill for the treatment of low-grade ore

PROPERTY MAP OF THE BUTTE DISTRICT

MONTANA

Butte.—The Butte & Superior company has increased the capacity of its No. 3 hoist to operate at a depth of 5000 ft. No. 3 shaft is now 2300 ft. deep and a cross-cut to the Rainbow lode has been completed. Drifting has given encourag-

next spring if a suitable process can be found. After a number of experimental tests on the gold-silver-lead products from the Eureka-Croesus mine, the company has decided that they have found a method that will prove effective for the treatment of the high and low-grade ores combined.

Las Vegas.—The Martin-Ronnow gypsum mine, seven miles north-east of Las Vegas, has been sold to J. H. Pierce, of Los Angeles, for a price reported to have been \$25,000. It is said that a narrow-gauge railroad is to be built from the mine to Las Vegas, that a reduction plant is to be built, and that 400 tons of ore will be shipped daily.

Reno.—Ore assaying from \$25 to \$75 per ton in silver, copper, and gold has been opened on the 300-ft. level at the mine of the Standard Metals Co. The mill is being put in shape for operation, according to A. L. Chappell, manager. —An inclined shaft has been sunk for 65 ft. in a shoot of high-grade silver ore on the Hager-Keefer property. —The shaft of the Black Panther mine has reached a depth of 220 ft. and will be sunk to the 500-ft. point.

Virginia City.—The Comstock-Florida company, of which G. S. Clark is president and general manager, is cleaning up the old tunnels and drifts on the Florida group of claims, preparatory to a thorough exploration of the property.

NEW MEXICO

Lordsburg.—The total ore-shipments from the district during the month of December 1920 amounted to 73 carloads, or 3575 tons of an approximate value of \$70,000. The total ore output for the year 1920 was 1108 carloads or 56,284 tons of approximate gross value of \$1,125,680.

OREGON

Grants Pass.—The recent sale of the Boswell mine to Thomas Norden and associates of Seattle has resulted in the incorporation of the Boswell Mining Co. The new owners will erect modern equipment on the property at once. This mine is situated 30 miles south of Grants Pass in the Sucker Creek district, a comparatively new gold-producing area in this region. From the present working, which is not over 20 ft. in depth, \$46,000 in gold has been taken.

A decree in the Circuit Court of this county in the suit of Rowan v. Barton is in favor of Barton and associates. Two years ago a receiver was appointed for certain chrome mining properties and the personal property held by the Bartons, upon the petition of Rowan, who alleged that a partnership existed between the Bartons and himself and that he was entitled to a portion of the proceeds from the chrome mines. By order of the Court appointing a receiver assets totaling some \$50,000 were tied up. The decree released all of this property and holds that a partnership never existed, that Rowan has no interest in the proceeds from the war-time mining operations of the Barton brothers, and that the appointment of a receiver was wrongful.

WASHINGTON

Stevens County.—Between 400 and 500 men have been laid off by the three big magnesite companies at Valley, 50 miles north of Spokane. These are the Northwest Magnesite Co., the American Minerals Production Co., and the American Refractories Co. Unfortunately this constitutes a real shut-down and not merely a curtailment, as, with the exception of the American Mineral Production Co., no production whatever is being made, the few men still left being employed simply in repairs. The exception noted is the running of a small pioneer kiln which produces some 100 to 150 tons per month of calcined magnesite for the Eastern flooring and stucco trade. A large kiln is practically completed, with a capacity of 1000 tons per month. Austria is now supplying nearly the entire demand in this country, and the shut-down will undoubtedly last till a protective tariff is secured.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Charles Janin has gone to Washington.

Harry H. Webb is at the Fairmont hotel.

G. C. Bateman has moved from Toronto to Cobalt.

W. A. Carlyle has returned from England to Ottawa.

Frank E. Nye, of Boston, is at Battle Mountain, Nevada.

Donald F. Irvin will sail from New Orleans on February 9 for South America.

John A. Burgess is making a geological examination at Searchlight, Nevada.

H. G. Nichols is now with the Canada Copper Corporation, at Copper Mountain, B. C.

Charles Butters sailed from San Francisco on January 19 on his way to Iquique, Peru.

D. W. Brunton left Denver on January 16 on a pleasure tour to the West Indies and Panama.

G. A. Joslin, of Salt Lake City, was in San Francisco this week on his return from Los Angeles.

James Frame has left Boston to examine silver mines near Chalchihuites, in Zacatecas, Mexico.

Will H. Coghill, of the U. S. Bureau of Mines, is studying the sludge problem in the Wisconsin zinc region.

Amor F. Keene, of New York, was here last week on his way to the La Grange mine, near Weaverville, California.

Livingston Wernecke, in charge of prospecting operations for the Treadwell companies in Alaska, was in San Francisco last week.

A. W. Allen has arrived in New York on his way from Chile by way of London. He is expected in San Francisco next week.

A. E. Drucker has accepted an appointment on the faculty of the University of Illinois, Department of Mining Engineering, to take effect on February 1.

O. Hallingby, formerly superintendent for the La Salle Mining Co., has become a member of the faculty of the Michigan College of Mines at Houghton.

C. H. Munro, who returned recently to San Francisco from the Federated Malay States, is returning thither on a two-years contract with the Yukon Gold Company.

C. V. Corless, manager for the Mond Nickel Co., has been nominated for president of the Canadian Institute of Mining and Metallurgy. He sailed for London on December 29, but will return shortly.

R. T. White, formerly manager for the Balaklala Copper Co., was in San Francisco this week on his way from Chile, where he was the manager for the A. S. & R. Co., and has left for a holiday in Florida.

C. H. Macnutt has resigned the resident management of the Black Lake Asbestos & Chrome Co. to take charge of the Vimy Ridge property of the Bennett-Martin Asbestos & Chrome Mines, at Coleraine, in Quebec, Canada.

Herman Garlich, a notable metallurgist, died on January 8 at his home in Brooklyn, New York, at the age of 61. He was born at Brooklyn in 1859, his father being then the pastor of a Lutheran church. After graduating from the Columbia School of Mines, in 1880, he went to Colorado and worked as a U. S. Deputy Mineral Surveyor. Between 1884 and 1908 he served as metallurgist at a number of important smelters, including those at Aurora, Denver, Velardeña, Kansas City, and Newark. During the War he worked for the Government as advisory metallurgist at "a dollar a year". He was a man of high integrity and kindly character, and will be mourned by many friends in the West.

THE METAL MARKET

METAL PRICES

San Francisco, January 18

Aluminum-dust, cents per pound	65
Antimony, cents per pound	9.50
Copper, electrolytic, cents per pound	14.00-14.50
Lead, pig, cents per pound	5-6
Platinum, pure, per ounce	\$73
Platinum, 10% iridium, per ounce	\$105
Quicksilver, per flask of 75 lb.	\$50
Spelter, cents per pound	8.25
Zinc-dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

January 17.—Copper is quiet and firmer. Lead is active and stronger. Zinc is dull and easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

OIL-WELLS IN THE UNITED STATES

The number of producing oil-wells in the United States on October 31, 1920, was approximately 258,000, according to figures compiled by the U. S. Geological Survey. Production averaged 4.98 bbl. each per day. On this basis production of the wells for one year would be 463,680,000 barrels.

The largest number of producing wells is in Pennsylvania, which is credited with 67,800, and here the smallest average production is recorded, namely, 0.3 bbl. (approximately 12 gal.) per well per day, with the exception of New York, an unimportant producing State. Oklahoma has 50,700 producers, with average daily output of six barrels per well. Ohio is third with 39,600 wells producing five barrels daily per well.

Texas and California, which were the leading producing States in November, with a total output of 9,489,000 bbl. and 9,340,000 bbl. respectively, have both a comparatively small number of wells, but with large average production. Texas has 11,100 wells, 9400 of which are in north and central fields and 1700 in Gulf Coast. North and central producers have an average daily output of 22.9 bbl. each, while those in the Gulf average 49.7 bbl. Californian wells number 9490 and average 32.3 bbl. each.

The following table shows the approximate number of producing oil-wells, by States, as of October 31, 1920; the approximate production of each well per day; and the estimated total production by States for November, giving an idea of comparative importance of the States as producers:

	Number of producing wells	Daily average output, bbl.	November actual output, bbl.
Texas, central and north	9,400	22.9	6,714,000
Gulf Coast	1,700	49.7	2,775,000
Total, Texas	11,100	27.0	9,489,000
California	9,490	32.3	9,340,000
Oklahoma	50,700	6.0	9,031,000
Kansas	15,700	7.4	3,578,000
Louisiana	2,700	31.8	2,815,000
Wyoming and Montana	1,000	55.9	1,432,000
Illinois	16,800	1.7	848,000
Kentucky	7,800	3.2	734,000
West Virginia	19,300	1.1	658,000
Pennsylvania	67,800	0.3	603,000
Ohio	39,600	5.0	602,000
Indiana	2,400	1.1	81,000
New York	14,040	0.2	75,000
Colorado	70	4.1	8,000
Total	258,000	4.98	39,090,000

MONEY AND EXCHANGE

Sterling, dollars:	Cable	3.77
	Demand	3.78
Francs, cents:	Cable	6.38
	Demand	6.40
Lire, cents:	Demand	3.57
Marks, cents		1.69

Eastern Metal Market

New York, January 12.

Practically all the markets, except perhaps zinc, are stronger in tone but prices are not substantially higher though the tendency is in that direction.

Copper demand is a little better and the price situation a little stronger.

The pronounced strength in sterling exchange has stimulated prices in tin.

The lead market is growing stronger each day and prices are higher.

Demand for zinc remains quiet but the price-level is stationary.

Antimony is inactive.

IRON AND STEEL

Ten days of the new year have brought little change in the rate of mill operations or in the buying of steel. A few plants which shut-down completely before the holidays have resumed in part, but it is frankly said that even such activity will be short lived unless larger demand develops this month. The Steel Corporation continues to operate most of its mills at more than 90 % of full capacity, with indications that this condition will be maintained through the winter.

How long the Steel Corporation price level will be held is the uppermost question. In the few tests that have come, the corporation has adhered to its schedule, though on plates in particular other makers have quoted 2.50c., representing a cut of \$3 per ton.

December steel output fell off but 11% from that of November, so that an ingot production of 40,000,000 tons for 1920 is indicated, against 33,700,000 tons in 1919.

COPPER

The improvement in the market is one of sentiment rather than demand. The better feeling is pronounced but is probably largely psychological. It may be said, however, that the price situation is firmer, the cheaper lots and quotations having largely disappeared. There is less tendency to cut values or to scramble for business. Inquiry is also on the mend. In the face of the fact that heavy consumers are well stocked with 15 to 18c. metal and that business is still slack in finished lines, no buying of consequence is looked for in the near future. We quote the market for electrolytic copper at 13c., New York, for early delivery, and at 13.25c. for first quarter, with Lake copper at 13.25c. and 13.50c. for the same respective positions.

TIN

There has been a marked improvement in this market. Consumers and dealers have entered the market and there has been a revival in buying of some proportions. Early last week sales were made of shipment from London and of future shipments from the East and at the time more could have been sold, but no large quantities were offered. There was a fair number of sellers and competition was quite keen. As the week progressed, demand broadened until toward the end the market turned sluggish, due to higher prices in London and the value of sterling. Sentiment is decidedly better. On Monday, this week, there was more inquiry from which some sales resulted. The quotation for spot Straits has steadily advanced the last week until yesterday it stood at 38.75c., New York, against 36c. a week ago. A strong factor has been the sharp rise in the pound sterling which is predicted to go to \$4 soon. Arrivals thus far this month have been 265 tons with 2400 tons reported afloat. A feature of the annual tin statistics is the 1920 output of American electrolytic tin which was 14,613 tons against 11,596 tons in 1919, and only 3845 tons in 1916.

LEAD

This market is the strongest and most active of any. There exists a good demand which has resulted in substantial sales. As a result prices in the outside market have hardened until they are higher than the leading interest. The latter still quotes 4.75c., New York, but an advance has been expected before this. It is believed that this is a nominal one and that the American Smelting & Refining Co. is not taking any orders. We quote the outside market firm at 5c., New York, and 4.85c., St. Louis. Advice from one dealer is to the effect that the London market should be carefully watched so as to avoid too rapid an advance here, even if no large surplus has recently been accumulated. This course may forestall further imports.

ZINC

This market is the most sluggish of all. Demand does not increase and there seems very little present prospect of a buying-movement. A stronger market in London is the most encouraging feature, as well as the fact that domestic production is cut down and that prices are below cost. Such relations cannot continue for a long period. Galvanizers are not busy and hence buying is only for prompt needs and producers of zinc are not eager sellers. We quote prime Western for early delivery at 5.50 to 5.60c., St. Louis, and 6 to 6.10c., New York. Quotations for forward positions are not freely given if at all.

ANTIMONY

The market is very dull with wholesale lots for early delivery unchanged at 5.20 to 5.25c., New York; duty paid.

ALUMINUM

This market is quiet and unchanged with virgin metal, 98 to 99% pure, quoted in wholesale or 15-ton lots for early delivery at 28.30c. f.o.b. producer's plant by the leading interest and at 22 to 23c., New York, by other sellers.

ORES

Tungsten: There is almost no business. Dealers and speculators are doing a little. The advance in the pound sterling has stiffened quotations and made them at least firmer. The ferro-tungsten market is also quiet and unchanged.

Molybdenum: There is no market. In the absence of any buying no quotations are available.

Manganese: Stocks are heavy and prices entirely nominal around 40 to 45c. per unit, seaboard, though this has been and can be shaded in special cases.

Manganese-Iron Alloys: The ferro-manganese and spiegel-eisen markets are stagnant and prices are nominal. For the former \$110, seaboard basis, is the asking price with \$45, furnace, the quotation for spiegel, but this can be and has been shaded. Re-sale ferro-manganese has sold around \$50 to \$100, but an offer of \$98 the last week did not bring out any alloy.

Under date of January 11, the market letter of Srinivas R. Wagel says: "The market for silver opened firm, owing mainly to the support from India. The advance in the London price since the close of last week was only 1d., but the heavy rise in sterling exchange made New York very firm. Owing to the arrivals of small amounts from the Continent and speculative activity in China, the market declined and closed weak. The Chinese markets were fairly active. Speculative sales tended toward weakness, although they closed steady. The silver stock in China is unchanged."

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A RECORD OF LONG SERVICE FOR MINE-LOCOMOTIVES

An electric mine-locomotive that has a unique record for longevity and service is at present operating in the mine of the Union Pacific Coal Co. at Rock Springs, Wyoming. The locomotive was built by the Thomson-Houston Co. and was put in service at its present location 27 years ago. It has been giving continuous service ever since, records kept by the coal company showing that it has hauled 3,712,500 tons

been used on a very rough road, but there has been comparatively little trouble due to the breakage of springs.

It has also the low record among the locomotives used in the mines of this company for repair charges, and consequently in cost per ton of coal hauled. In fact it is held to be just as efficient in operation as any of the recently designed locomotives in their service. The feature that is held largely responsible for the low upkeep is the use of the semi-elliptical leaf-spring construction. It is interesting to

Electric-Locomotive at the Union Pacific Coal Mine

of coal over an average distance of 1.5 miles in that time, or a total of 5,568,700 ton-miles.

The locomotive is type GLM-30-6 terrapin back, 500-volt, with a speed of eight miles per hour. Its capacity is 9 tons, with a 3000-lb. draw-bar pull, and the wheel diameter is 38 inches.

The locomotive is equipped with one motor having a single field-coil and the old Gramme ring armature. The original field-coil is still in service and has never given any trouble. Two armatures have been used, one the original furnished when the locomotive was bought, and another spare one. The commutators are very much smaller than those used at the present time for 500 volts, and five of them have been worn out in service. The original control was the semi-circular disc type, which has since been abandoned. The present control is an R-22 controller and a Jeffery pan-ake resistor. The original brake rigging is still in service, and the gears have also given excellent service, as only three of them have been worn out.

The locomotive is equipped with semi-elliptical leaf-springs, which support its weight on the journal-box. It has

note in this connection that the General Electric Co. has returned to this design in its locomotives, with the addition of an equalizer-bar to distribute the weight more evenly.

CHICAGO PNEUMATIC MINE-CAR COMPRESSORS

The air-compressor outfit illustrated has been designed particularly for the mining industry. Its usefulness is not confined to that field, since quarries and large construction projects having a system of narrow-gauge tracks will find a large and varied use for this machine. The flexibility and economy of this outfit are obvious, since the car can be moved to the point of distribution, resulting in the elimination of line-losses and troublesome and expensive systems of piping. Leakage and friction losses are inevitable where the air is used at a great distance from the compressor, and where the piping is of a temporary nature and subject to abuse, as is frequently the case in newly worked portions of a mine, the line-losses are enormously high. The economy effected by the elimination of these losses far more than offsets the difference in efficiency between one large unit

and a number of small units, to say nothing of the convenience of the portable outfit and the saving in time, expense, and trouble in laying air-lines in newly worked sections of the mine.

The outstanding features of Chicago pneumatic compressors are ruggedness, simplicity, efficiency, totally enclosed construction, and 'simplate' flat-disc air-valves. The compressor is of the horizontal single-stage type and possesses all of the superior features of the company's standard straight-line compressors. It is hopper water-cooled and geared to an electric motor by means of a sturdy herring-bone gear and pinion. The complete outfit, consisting of compressor, air-receiver, 'differential' unloader, electric motor, and starter, is mounted on a substantial mine-car which is readily adjustable to suit any track gauge commonly found in mines.

The compressor is driven by an electric motor, through herring-bone gear and pinion. The gear is cut from a solid cast-iron disc of sufficient weight to give the proper fly-

Compressor Mounted on Mine-Car

wheel effect. The pinion is of forged steel. It is a well-known fact that herring-bone gears run more smoothly than spur gears, and also work silently without vibration. The gear and pinion are entirely enclosed by cast-iron gear-case, and run in a bath of semi-fluid grease which partly fills the bottom half of the case.

The customary electrical equipment includes a 230-volt direct-current moisture-proof motor of standard make, a suitable hand-starter with low voltage release, and a line-switch properly fused to provide overload protection. Electrical equipment can also be supplied for alternating current of any standard voltage. Suitable drip shields are provided to prevent water from dripping from the roof of the mine onto the motor or equipment.

A horizontal receiver, made from 60,000-lb. tensile-strength steel, is clamped to the deck of the car by two steel straps and is furnished with a pressure-gauge and pop-valve, set to 110 lb. pressure.

The compressor and equipment are mounted on a sturdily constructed mine-car having a strongly ribbed deck. The car is provided with forged steel axles of such length that the wheels can be adjusted to run on 36 to 42-in. gauge tracks. The wheels are of cast-iron, bushed with bronze bushings, and are held in position on the axles by adjustable collars. The wheel base is sufficiently short to readily negotiate sharp curves.

N. E. Otterson has been appointed Eastern manager for the Clyde Iron Works Sales Co. distributors of hoisting machinery manufactured by the Clyde Iron Works of Duluth, Minnesota.

CONCERNING WELDED TANKS

"The manufacturers of rectangular welded tanks," writes a mechanical engineer in recent issues of 'The Boiler Maker' and 'The Welding Engineer', "are apparently following the same designs for the staying as were used when the tanks were riveted. The result is that the tanks fail by opening the welds at the corners, which soon commence to leak and, not being repairable, have to be scrapped . . . Unfortunately there is no practicable way of repairing a welded joint."

Human expression falls easily into the general statement form, and it is not surprising that conclusions supported by superficial evidence are often in error, as there is always danger of confusing the exception with the rule. This appears to have occurred in the deductions drawn in the above statements. That the conclusions had for their basis only the weakness of an isolated instance, a solitary second-hand tank of a type made before special engineering study had been applied to welded tank construction, seems certain from subsequent statements in a letter written by the author of the original published article.

"I regret to be unable to say," writes the engineer, "which process was used in welding the tank mentioned in my article. This tank was used to hold the feed-water on a steam-shovel, and both shovel and tank were second-hand when they came under my attention.

"Speaking from memory, I should say the tank was about 10 ft. high, 6 ft. long, by 2½ ft. wide, of ¾-in. plate, and of practically rectangular shape. The tank was open at the top, or rather I ought to say there was a hole about 18 in. diam. in the top plate, and it was filled with water about once per day, and the boiler was fed from it as required. The pressure on the sides was only that due to the head of water, that is, 10 ft. as a maximum; but the bracing was so badly designed that the bulging of the sides was quite perceptible

when the tank was being filled."

In the words of a welding-engineer to whom this letter was referred: "That is certainly the most superficial basis for damning an industry that has ever come to my attention!"

Of course the author-engineer had no intention of "damning an industry", as evidenced in another of his statements, namely: "This gives the welded tank a bad reputation—which it does not deserve, the fault being entirely with the weakness of the bracing." Basing his assumption that all welded tanks are poorly braced on the premise of the single instance cited, he proceeded with the development of a series of equations to determine the bracings necessary under varying conditions as to dimensions, materials, and pressures.

The welding industry will not pass unchallenged the inference that weakness is inherent in welded-tank construction. Quite a contrary position will be taken by those engineers who have specialized for some years past in the application of welding to manufacture of tanks. Tanks welded by the oxy-acetylene process are being built in many parts of the United States, and they are at once so economical and so satisfactory that they are very largely displacing riveted tanks. They withstand very much greater pressures than the water pressure in the tank previously noted, and after proper test and inspection are accepted everywhere as the highest type obtainable in tank construction.

It should be made very clear, and it cannot be too positively stated, that welded joints can be repaired, and very easily and effectively, by the oxy-acetylene flame, though the occasion for such repairs, as welded tanks are now constructed, is practically non-existent.

THE GENIE OF THE BOTTLE

LIKE the Genie from the "Arabian Nights", Prest-O-Lite is a wonderful force confined in a small cylinder.

It is subject to the command of its master—the trained welder and cutter. Under his direction it performs feats of wonder—anywhere, at any time.

In the subway builder's excavation, in the floating dry dock, in fact *any place—any time* where welding and cutting metals are required, the ready portability of Prest-O-Lite is an asset of genuine worth.

Ask us about the service plan of the Universal Gas with the Universal Service.

THE PREST-O-LITE COMPANY, Inc.

30 East 42nd Street, New York, N. Y.

Balfour Building, San Francisco

In Canada—Prest-O-Lite Co. of Canada, Limited, Toronto

T. A. RICKARD, Editor

TARIFFS on mineral products under Schedule C are being asked from Congress as follows: 10 cents per pound on antimony in ore, matte, and antimonial lead; 50 cents per pound on molybdenite in ores and concentrates, with \$1 on the molybdenum in alloys; 50 cents per pound on quicksilver; \$10 per unit of tungstic oxide in ores, concentrates, or compounds, with \$1 per pound on the tungsten in ferro-tungsten; two cents per pound on lead in whatever form imported; and two cents per pound on the zinc in ores containing 25% of zinc or more, 1½ cents per pound if the ore assays under 25% in zinc; 2½ cents on zinc in blocks, pigs, zinc oxide, pigments not containing lead, and 3½ cents on zinc in sheets, strips, plates, or coils. Hearings before the Ways and Means Committee are being held for the purpose of obtaining information on the supposed need for these tariffs.

THE existence of the Mining and Metallurgical Society of America is made known annually by its bestowal of a gold medal on some worthy member of the profession. This year this society has done itself proud, as the saying goes, by awarding its medal to Mr. Charles W. Goodale "for his distinguished service in increasing safety in mining and metallurgical operations", more particularly at Anaconda. We can think of several reasons for giving Mr. Goodale a medal, the chief of which is that all his life he has been an exemplar of all that is honorable and of good report in a mining engineer. The Society has also distinguished itself by electing Mr. J. E. Spurr as president in succession to Mr. Waldemar Lindgren. We are compelled to acknowledge that, although we demur to the continued existence of the Society, which we deem supernumerary as an organization of technicians, we concede gladly that it consists of a coterie of men in whose company we would be glad to find ourselves at any time.

BIG men sometimes say small things. Mr. Charles M. Schwab in a public speech refers to the Panama Canal tolls and deplores the fact that "at present our ships must pay the same tolls at the Panama Canal as ships of nations that did not spend one cent to build it and are not contributing one cent of taxes to maintain it! It is said that a certain treaty makes this necessary: Well, if I had the handling of the situation, I'd damn soon get rid of the treaty!" As if the honor of the United States

were not worth more than any amount in tolls, and as if our Government were to regard a treaty to which it had signed the name of this nation as another "scrap of paper". If it be inequitable, it will be proper to ask for a re-consideration and possible friendly amendment of the treaty, but for a man in Mr. Schwab's position to propose without further reason to "damn soon get rid of it" is a very different thing and one that proves him unfit for leadership in national affairs. Public men should refrain from making careless statements; their status carries with it a measure of personal responsibility that they are not warranted in ignoring.

A DISPATCH from Washington says that the House Committee on Appropriations has authorized the expenditure of \$3900 for the continuation of the U. S. Assay Office at Salt Lake City during the year 1921. Mr. Raymond C. Baker, Director of the Mint, reported that during the past year \$20,219 worth of gold and silver had been received at the Salt Lake office and that the expenses had been \$4172 and the earnings \$743; he recommended, quite rightly, that the office be discontinued since bullion can be sold either in San Francisco or in Denver. Obviously the refinery-man at Salt Lake City must be in a state of innocuous desuetude most of his time. The only possible reason for such performances on the part of Congress is to make soft jobs for the friends of good political wire-pullers. We know nothing of the personnel of the staff of the Salt Lake assay-office and our criticism is entirely impersonal; the trouble is with the system that makes such unjustifiable appropriations possible. The fact that the amount is small does not make the glaring waste of public money any less reprehensible, especially at a time when the Government should be setting an example of thrift.

PASSAGE of the bill providing for appeal to the Court of Claims on the part of dissatisfied War Minerals claimants has been opposed by the Secretary of the Interior in a letter to the House Committee on Mines and Mining. The Secretary, Mr. John Barton Payne, says that his department has given the claimants every opportunity to present their cases and has endeavored to reach a just and equitable conclusion under the law. Serious controversy has arisen over the interpretation of the phrase "request or demand", in which the Secretary of the Interior has followed the opinion given by the At-

torney General, as also over the question whether the purchase price of a mine be compensated under the Mineral Relief Act. Mr. Payne considers the pending bill, for appeal to the Court of Claims, too broad; it would, he thinks, permit a re-examination of all claims. "It is doubtful", he says, "especially in view of the completion of the work, whether any further legislation is wise; but if Congress thinks it is, I suggest the appeal be limited to questions of law, and that further appeal be allowed to the Supreme Court". Mr. Payne, we may mention, is a lawyer by profession. He asserts that the "large majority" of the claimants are satisfied and that the Commission has "endeavored to carry out the law in a liberal spirit". That is a matter of opinion; we happen to have heard many opinions of a contrary nature. The Attorney General's dictum as to "request or demand" seemed to us, and still seems to us, mistaken and inequitable, and an attempt on the part of the Government to evade a just obligation.

ELSEWHERE in this issue we publish a brief but interesting article by Mr. Will H. Coghill, in which he urges that the Western engineering schools model their methods of instruction after the colleges and universities in the Eastern States; and he criticizes with good grace, since he declares that he himself is a "victim of the drop-forging system", as he styles the Western plan. His principal objection is the tendency to "cram" the student with "practical courses" to the exclusion of economic and purely cultural subjects that are part of a liberal education. We discussed this question at some length in our issue of August 14, advancing the opinion that engineering curricula in all our mining schools, both East and West, were being revised to include more of these non-technical courses. Mr. Coghill presents some interesting data showing the proportion of graduates from Columbia, the Massachusetts Institute of Technology, and three unnamed Western schools that had been honored by 'Who's Who' for 1913-1914. The figures, beginning with Columbia, as expressed in percentages are 8.3, 4.4, 0.8, 0.7, and 0.0. Some might be inclined to question whether enumeration in the exclusive pages of 'Who's Who' is the best test for determining the successful mining engineer, but granting that it is, we venture to suggest one point that may invalidate the conclusion appearing on the face of the figures. It will be noted that graduates from 1882 to 1905 are included; but, whereas Columbia and Massachusetts began graduating engineers in the early 'eighties and had a number of engineering alumni by 1895, it is doubtful if the Western schools, the identity of which we can only surmise, had more than a dozen graduates prior to 1895, if indeed they had any at all. Accordingly, the older institutions would have a decided advantage in view of the fact that the reputation and prominence enjoyed by the elect of 'Who's Who' generally are attained in the years of maturity. A fairer comparison apparently would be obtained if only the men finishing their college course since 1900 were considered. The large university, with its rich tradition,

affords the student evident advantages that are not to be had in the smaller and newer school of mines; it has the stimulating atmosphere of culture and learning; it can attract the mature, the brilliant, and the inspiring teacher; it gives its graduates a certain prestige. These things may help, but in the end the result of any education depends largely on the individual himself; the good that he gets from his school and university will be just about proportionate to the energy and effort he applies regardless of those who direct the work; and if his education ends with his college days, if he stops studying when he obtains his sheepskin, he will never make any great success as an engineer whether his alma mater be Columbia, Chicago, Houghton, Golden, or California. We are inclined to think that the excellent educators who are in charge of most of our Western mining schools realize their disadvantages as well as their advantages; that they recognize their shortcomings; that they are alive to the progress being made elsewhere; and that they are striving to make improvements as earnestly as the administrators of the larger institutions in the East; indeed it is quite possible that many changes have been made at Mr. Coghill's own school since he and his classmates received the impress of the die in the "drop-forging" process.

The Irish Question

We happen to know something about the British empire, having sojourned in London and Melbourne, and we also know something about the Irish republic, having lived in New York and San Francisco, therefore we venture to refer to the Irish question, which some people are trying, not unsuccessfully, to make an American question. It is a subject that bristles with unpleasant points but it is one that no honest editor can ignore indefinitely even if he might wish to do so, because it is producing consequences much too grave to be disregarded by serious commentators on current events. The foremost objection to agitating the Irish question in the United States is that it introduces a non-American issue among our people and tends to disintegrate national solidarity by inciting a controversy that makes an appeal to racial prejudices at the very time when an earnest effort is being made to Americanize the alien elements in this country. The climax of Irish propaganda is the advocacy of a blood feud between the Irish and the British, all over the world and more particularly in this country, in speech made publicly in New York by a Mr. Boland, who is described as the secretary of the so-called president of the Irish republic. If this Mr. Boland were to advocate anything so foolish on a platform in Cork or in London it would be none of our business, but that he should incite American citizens of Irish birth to kill American citizens of British birth in the United States is very much our business, as it should be the business of good citizens. After all, the Irish question is no more our affair than the Santo Domingo or the Alabama question is one for the British. Some of our public men believe it best for us as a nation to keep out of Europe.

entanglements, and they quote Washington in support, yet a group of Senators has seen fit to interfere in the affairs of a friendly nation, and members of the Massachusetts legislature have sent an insulting message to the Prime Minister of that nation, one that only recently was our comrade in arms against the common enemy. A notoriously pro-German editor, Mr. Oswald Villard of 'The Nation', has appointed a partisan committee to enquire into the government of Ireland, and this committee is now in session at Washington. A mob of Irish-Americans flying an Irish flag attacked a club in New York because it celebrated Armistice Day by displaying the British flag in company with the French and American flags. It is not illegal to display a foreign flag, as everybody knows, because we have had as many as twenty of them in public places during recent years. It is illegal to assault a private residence. The leader of the Irish rebellion, a man of Spanish birth and born in New York, has been received formally and given civic honors by the mayors of New York and San Francisco. Now, gentle reader, imagine that corresponding acts had been performed in Great Britain. Suppose the leader of a rebellion in Alabama or Santo Domingo had been given the freedom of the City of London; suppose the editor of the London 'Nation' had appointed an anti-American committee to investigate the lynching of negroes or the exclusion of Japanese; suppose the House of Lords had discussed a resolution criticizing our administration in the Philippines; suppose the legislature of Quebec had sent an insulting message to President Wilson; suppose the Carlton Club in London had been attacked by a mob flying a Japanese flag because the Club had displayed the bear flag of California; suppose a Texan were to make a speech in London advocating a vendetta between the Canadians and the British. Try this on your piano, Mr. Reader, and see how you like the tune! The imagination of any sensible man, of course, recoils at these suppositions; to state them is to make them a nightmare of primal absurdity. Yet their converse has actually happened. Is it not time to call a stop to the Irish propaganda in our midst? Ireland has wrongs and we deplore them; the Irish are unfortunate in their relations with Great Britain, and we regret that; but for the time of a generation the Liberal statesmen of England have tried honestly and persistently to arrange their troubles, and many, from Gladstone down, have wrecked their political reputations in the effort. It is a domestic quarrel, which few of us understand, and it is one in which our interference only makes more mischief, as usually happens when outsiders interfere in a domestic quarrel. We are not helping the cause of the Irish by sowing dissension among our own people; it may fairly be doubted whether we are helping them by irritating the British; we are only introducing a non-American issue in a way to create factional disturbance among ourselves, as if we had not enough difficulties, economic and political, to engage our best attention. Or shall we go on with this European entanglement and boycott all British goods, as has been suggested by sundry gentlemen at Chicago? Before we do that, let us remind ourselves that Great Britain is our

customer to an extent equal to our trade with all the rest of the world put together. This sounds a sordid note; then let us remember that of the British armies in the field, with us, England gave one in every seven of her population; so did Scotland; whereas Ireland gave one in 26. Whether we went into the war to keep the world safe for democracy, or to help England, France, and Belgium, or to resent the insulting acts of Germany—whatever the reason, the fact remains that while our boys were fighting in France the Sinn Feiners were stoning American sailors in Cork. It was not the Irish that did this, only a faction among them, it is true, but it is the appeal of this faction to our hyphenates that is making trouble, and threatening to make it worse. The transfer of European domestic quarrels and racial vendettas to this country is to be reprobated, and even resented, because every time it is done it tends to create a cleavage among us, and that, we submit earnestly, is to hinder, if not to destroy, the Americanization of our heterogeneous population, upon the friendly assimilation of which depends the present welfare and future destiny of this nation.

How Many Hours?

The results obtained by substituting three eight-hour shifts for two of twelve hours each in industries where some of the processes are of such a nature that operation must be continuous are discussed in a recent issue of the 'Journal of the Engineers Club of Philadelphia', a publication, by the way, in which we frequently find something of more than ordinary interest. In the principal paper Mr. Robert B. Wolf presents precise data regarding sundry sulphite paper-pulp mills, in which the old two-shift system had been replaced by three shifts. In one plant the production had been increased from 42,000 to 110,000 tons per year, without the addition of a single digester for cooking the pulp; the quality of the product had been improved from the poorest to the very best; and a net reduction of between \$5 and \$6 in the cost had ensued. Other factors enter into the attainment of this improvement, but Mr. Wolf declares that the mental and physical alertness of the attendants resulting from the introduction of the shorter working period was mainly responsible. Under the older system the men were fatigued and indifferent; neither their physical condition nor their mental attitude was favorable for producing the best quality nor the maximum quantity. The wages paid for eight hours of work were exactly the same as had been paid for twelve hours, so that the improvement necessarily came through increased efficiency on the part of the operators. Mr. Wolf confesses that the change was forced on the officials by the men and that the fortunate outcome from the company's standpoint was entirely unexpected. Mr. Harrington Emerson, one of the deans of our so-called efficiency engineering, gives the following significant statement apropos of a similar change: "Very recently we made a study that covered eight months in one of the large steel mills in the West, where they were considering changing over from twelve hours to eight hours; three different conditions representing three dif-

ferent ideals were accepted. The philanthropists demanded that the hours should be reduced 33%—from the twelve hours to eight. The workers said, 'We are willing to consider the eight-hour day provided we get just as much for the eight hours as we before earned in the twelve; if you can accomplish that we shall accept the reduction in hours, but not otherwise. We do not propose to have our daily earnings reduced by any plan such as reducing from twelve hours to eight'. The demand for the eight hours did not come from the workers; it came entirely from the group I have called philanthropists. The third group, the production men, said, 'We have no objection to your going over to eight hours, provided you do not increase cost nor curtail production'. The results of these three conditions were that the plant officials did succeed in reducing hours 33%, that the wages of the men were actually increased per day over 10%, that production increased more than 30%, and the costs of labor and overhead decreased more than 10%!' "

These are concrete illustrations; the conclusions are the result of authentic and accurate data; they are not the result of abstract theorizing or of academic study; they are facts. In a great many occupations a man can accomplish as much useful work in a year by working eight hours per day as he can if he works twelve hours every day. This is different from saying that he can do as much in eight hours as in twelve; the point is that fatigue is cumulative; the human machine becomes sluggish. The unfatigued worker does better work and faster work, and if there is a definite number of machines to be operated fewer men are required if they are alert and unfatigued. The result is greater production per man per hour. From every point of view twelve hours is too much time for any man to devote strictly to the performance of his daily work. Provided the work is of such a character as to demand constant attention and application of either mental or physical effort, the average man cannot long continue to do himself justice when spending half his time at his task. An exception might be made for the work of an attendant in a power-house whose duty largely is to be on hand in an emergency; but even if a man in such a position can fulfill the requirements with maximum efficiency for twelve hours per day he is necessarily neglecting definite obligations to his family, and, we venture to add, some perhaps less definite obligations to his own spiritual being and therefore to society at large. In so far as mining and its allied industries are concerned the eight-hour question is virtually a dead issue; except for isolated exceptions, eight hours is the standard maximum for a day's labor, whether it be done by daylight only or on rotating shifts in continuous operations. Doubtless the growth of labor-unions and the consequent persistent pressure on the part of employees was the most important factor in bringing about the change, yet it is safe to say that not one employer in a thousand would revert to a twelve-hour basis; and the reason is not his virtuous desire to be philanthropic, but rather the definite appreciation of the fact that he gets larger production and a better product for each dollar

invested in labor than he could possibly get with a twelve-hour day. But if eight is better than twelve, may not six be better than eight? The more radical labor leaders are clamoring for it; ultra-conservative employers hold up their hands in horror; and the thoughtful employers and efficiency engineers are seeking an answer based on fact. The traditional theory that the day naturally divides itself into three equal periods, one for work, one for recreation, and one for sleep, serves an excellent purpose in that it is an easy and convenient subdivision of time, but it is scarcely scientific. Mr. Emerson declares that he favors four equal periods, rather than three, which would mean a six-hour shift. Lord Leverhulme, who not many years ago was plain Mr. William H. Lever, successful manufacturer of soap, has written a book, 'The Six-Hour Day'. The conclusions that he has reached are based on actual experience in his own large plants at Port Sunlight, a remarkable industrial town in Great Britain, which is the pride of Lord Leverhulme's life and incidentally the home of Sunlight soap, a product that is known around the world. He is a man of acute intelligence and broad experience; he is a theorist, but a practical theorist; he does not presume to say that the six-hour day can be introduced immediately in every industry or under all circumstances, but he does show how it has worked to the advantage of everyone concerned in the enterprise that he directs. Those who oppose any consideration of a six-hour day for the man whose work is manual, or at least routine, declare that wage-earners already have too much idle time on their hands and that this breeds discontent. Perhaps there is truth in the statement; if so, there is something vitally wrong in our social system. Every human being should be able to appreciate comfort, a reasonable amount of leisure, an opportunity to participate in some of the more serious affairs of life outside the winning of his bread, and a chance to play. It is argued that many employers and executives work ten and twelve or even more hours, but if their day is analyzed it is found generally that a large part of their time is devoted to interviews during which they come in contact with new personalities and new ideas. This is very different from the constant application to repetitive performance of a routine task, even though the work may be neither disagreeable nor grueling. There is no question but that if every man and woman in the United States were to devote four hours each day to energetic and effective work, of the kind for which he was best suited, production of every kind would far exceed the need. The trouble is that most work is ineffective; it is inefficient; it is wasteful. But we are acquiring efficiency. In the household, in the office, in the factory, on the farm, and in the mine effort is being conserved. Great strides in the introduction and improvement of machinery have resulted in a remarkable saving of human energy heretofore wasted. Perhaps some day we shall have a universal six-hour day; it may come through systematic and sympathetic co-operation but never as a result of impracticable and visionary Socialism.

DISCUSSION

Alaska Gold Mines Co.

The Editor:

Sir—In your editorial of December 25 you seemed to support the policy of this company in continuing to run its plant in spite of a heavy operating loss and a hopeless mine. Many important reasons incline me to take the opposite view and to condemn unsparingly a policy that can only mean the complete ruin of the bondholders if persisted in.

As can be ascertained from any corporation directory, the Alaska Gold Mines Co. has a Maine charter and was organized in 1912 to acquire the Alaska Gastineau Mining Co. The mining ground, with a small mill and slight underground development, had been purchased by the latter company for three millions from the original promoters, so that all the later investment above this sum represents the cost of the new 6000-ton mill and power-plants plus the equipment and development of the mine itself. The Alaska Gold Mines Co. has issued, all at par, I believe, \$3,000,000 of mortgage bonds and \$7,500,000 of stock, or a total of \$10,500,000 of securities. Subtracting from this last sum the cost of the mine, we have \$7,500,000 as the recent capital expenditure, of which \$3,000,000 was raised by two bond-issues of \$1,500,000 each in March 1915 and March 1916.

From March 1, 1915, to January 1, 1918, the company paid the bond-coupons as they became due, but its "operating profit" failed to cover this interest completely during the last quarter of 1917, and evidently it never attempted to write off any sum at all for depreciation of plant during this brief solvent period. Since 1917 even the operating profit has been a minus quantity, and the bondholders have looked on helplessly while the company officials are wearing out their vast investment, in power, mining, and milling machinery, as rapidly as it can be done by a daily struggle to extract and treat 4000 or 5000 tons of hard rock from an Alaskan mountain.

In late 1917 it was given out by the directors—perhaps in good faith—that the ore was being extracted from a lean zone and that the then gross value, of \$1 or so per ton, would soon change for the better as the mine advanced into the regular ore-zone. However, the contrary has proved to be the case, and instead of dollar ore they are now treating 85-cent ore or even worse. As a representative of some bondholders, I first protested against this operating policy in June 1918, addressing myself to Charles Hayden, the company's president, and was rewarded by two courteous letters from B. L. Thane, the managing director, in which I was assured that arrange-

ments were being made to sell the power-plants to a local wood-pulp company and that an active search had already been in progress for two years through Hayden, Stone & Co. to find a new mine on which the company's mining and milling equipment could be utilized—a search that had been conducted with energy and extreme caution and, while still unsuccessful, might be expected to locate a winner almost any day. Relying on these sensible promises, I waited patiently, during the balance of 1918 and all of 1919, for some of them to materialize, but as the reckless operating policy still continued with constantly increasing quarterly deficits, I again wrote to Mr. Stone in January of last year.

This time I am answered by E. N. Skinner, as mining engineer for the company, in another courteous letter. But now there are no definite optimistic projects announced either power-plant sales or expected new mines. Instead, Mr. Skinner remarks:

"In this particular case all machinery and equipment that could possibly be moved and sold would not bring a very large percentage of the bond-issue, even if it were possible to receive factory prices for it where it stands, and furthermore, it is expensive to dismantle and prepare for shipment elsewhere.

"Referring to your inquiry about moving the plant to some other mine, the company would of course like to do that if they could find the suitable mine, but as yet they have not been able to do so."

As the three-million dollar bond-issue represents only 40% of the total cash investment in equipment, it is evident that originally the movable machinery alone must have cost nearly, if not quite, all of the bond-issue when one considers the vast quantity required for a capacity of 6000 tons daily by the mining and milling system in vogue. In the tidewater location enjoyed by this mine, its machinery can be dismantled and put on board ship for a small fraction of its value; and it is then ready to be transported to another property, on or near tidewater, in any part of the world at a moderate cost.

Regarding the suicidal operating policy pursued since 1917, Mr. Skinner remarks:

"You ask us to explain as to why operations are being continued, when the mine is being run at a loss, with the result of rendering the plant worthless from wear. As an engineer, you will appreciate that it would not conserve the assets very much to shut down the plants and let them go to ruin in idleness if there is any prospect whatever of keeping them going. If they were shut down, they would be an expense to patrol and guard against fire, etc., and it is well known that a plant of this

kind deteriorates more rapidly when idle than when in use; because when in use it has to be constantly maintained in operating condition."

On the contrary, my experience "as an engineer" renders me quite unable to appreciate Mr. Skinner's point of view. I have preserved sheltered machinery many years, as good as new, by the simple device of covering all unpainted iron parts with thick grease, and have seen other machinery exposed outdoors for many years without harm by taking the precaution to locate it, properly, on a dry foundation, and to re-paint it occasionally. In assuming that machinery can only be kept in good condition by running it constantly, Mr. Skinner evidently confuses hardware with flesh and blood, a gold mill with a traveling menagerie. He goes further in mystecism than even the Monists, for while the latter insist that every particle of inorganic matter is endowed with a soul, I have never heard that they considered that its health could only be maintained by regular and strenuous physical exercise.

The search of Hayden, Stone & Co. for a new mine, as described by Mr. Thane, must have indeed been "cautious", since it has been conducted four years without tangible results. But why this firm should be exclusively relied on to find a new mine for the company, Mr. Thane did not explain, nor does he give any reason for believing that they would turn over a good mine even if they happened to locate one. From the standpoint of mining promoters is not the Alaska G. M. Co. a 'has been'; and, as such, must not any attempt to revive its fortunes appear as futile as would the re-filling of a punched egg-shell or the restoration of a squeezed lemon?

Formerly I labored under the delusion that the management of any enterprise that defaulted the payment of its bond-coupons could be taken over by its bondholders; but to accomplish this the bondholders must get together for legal action, and this is no easy matter in a State like New York, where the company officials are allowed to keep secret the list of bondholders. I was informed by my bankers in New York that the only practical way for a bondholder of the Alaska Gold to proceed would be an expensive course of newspaper advertising, in order to ascertain the names of his fellow-sufferers from mine-wrecking management. Such a remedy being financially impracticable for any small bondholder, there is nothing for him to do but to take his punishment, as the professional promoters very well know.

Some time ago I had occasion to examine a mine in eastern Mexico on which a cross-cut adit had been run 150 metres, and then abandoned while still far from the old vein. At first I believed that the adit proved that the vein must have been considered valuable in its upper workings, but this belief merely indicated my ignorance of Mexican psychology. As I afterward ascertained, the main object of the adit had not been to find ore but to enable the local foreman to continue his profiteering at the expense of the peons, who were paid by an absentee owner. Similarly, the real reason why Alaska Gold has continued its vast operations for four years at the bond-

holders' expense may some day come to light. As you say, it "has no object in keeping its underground workings in condition for future mining". And as it has no other property to which it can migrate, it has no excuse "for continuing to mine in spite of an operating deficit with the desire to keep intact as far as possible the essential parts of the working organization". One might guess that the promoters had filled the Alaska Gold management with their friends or relatives and that operations were being prolonged for their benefit; but while such a guess might be plausible in Mexico, it would hardly be so in the United States, especially in view of the active demand for mining men that has existed since 1916. Indeed, the problem seems to be as insoluble as that of 'The Lady and the Tiger', which perplexed my youth.

ROBERT BRUCE BRINSMADE.

The Broad Lode Hypothesis

The Editor:

Sir—To anyone who has followed closely the subject of 'Apex Litigation' the mention of this subject must induce discussion; therefore I ask your indulgence for space to discuss a few points covered in the contribution signed A. G. Ologist in your issue of January 15.

Having run the gauntlet of cross-examination by many a shrewd lawyer, whose chief desire seemed to be to get a contradiction out of a witness, rather than an exact statement of the truth about physical facts, it has been impressed upon me that partisan statements on the part of a witness in an apex case is the worst kind of evidence and least likely to convince the Court. If it is ever possible to administer justice in these cases it must be by means of skilled engineers, employed by the Court, not by the litigants. In that case the matter of a strict definition of lode or vein would not matter so much. In fact, I believe that the attempt to frame an all embracing definition is practically hopeless and will be modified and probably materially changed, each time that a judge renders a new decision in an apex case.

The definition proposed is a good one but not unassailable, due to the fact that the words "sufficiently mineralized to warrant mining operations with reasonable expectation of finding ore" will be dependent on the personal equation. That which inspires reasonable expectation in one man will be looked upon pessimistically if not with disdain, by another. It is fortunate that hop springs eternal in the breast of the miner, otherwise we would surely have no prospecting and but little persistent development, except in those rare cases in which pay-ore is continuous and uniformly of a good marketable grade.

My own idea, and this is not the first time I have expressed it, is that the only real cure for the evil of apex litigation will be the adoption of the 'square' location and the sooner we come to that conclusion and make the change, the better we shall be regarded by our posterity.

engaged in mining. Mining is hazardous enough without being obliged to maintain one's rights in courts where, as Mr. Locke says truly "prejudice jumps to the front" and it is a fair prediction that all the definitions in the world will not serve the desired purpose of making the apex law so simple that "he who runs may read".

San Francisco, January 19.

F. L. SIZER.

The Refining of Oil-Shale

The Editor:

Sir—In July 1919, in my letter to you on the subject of oil-shale and low-temperature distillation, I said that methods which involved mass carbonization were obsolete.

Work carried on for over three months recently on a working scale has proved the correctness of my statement and has thrown much new light on the little-understood art of distilling and refining solid hydro-carbons. The process and retort adopted by the Carbonization Company avoid treating a compact mass of material into which heat has to be introduced at a high cost of B.t.u. By treating each particle in an unconfined or free condition, by cascading it through the heat medium, the result has been rapid heating of the particles and the easy evolution of the gaseous product. By being removed quickly the particles are saved degradation. These conditions, I venture to think, are two (among others) of the most essential to success and mean that a large throughput can be obtained at a minimum expense of heat while the product is in the best condition.

But the mechanics calling for the necessity of continuous operation, the arrangements to heat the material as above, successively, in zones, and up to temperatures of 1400°F. with the proper care of the gas and waste residue, as well as treating the material in a closed gas circuit, involved considerable and careful working out. However, in a simple horizontal retort, revolving at whatever speed is best, these requirements have been filled, not merely theoretically but in practice. The procedure is almost fool-proof, so flexible that it can be adjusted to any conditions likely to be required, utilizing 40% less heat than the old vertical methods, and allowing the operator to exercise his ability as a distillery artist to the limit. Apropos of which we have demonstrated this fact, which should help any engineers attempting low-temperature distillation, that every shale or lignite or coal has striking idiosyncrasies or characteristics peculiar to itself, which it is necessary to ascertain first in order to treat them properly. By way of example: of two shales apparently the same, one gave up 90% of its contents in 18 minutes at 600°F. and the other yielded 60% in 30 minutes, then stopped evolution until 920° was reached, when it took 70 minutes to get another 25% and so on in most cases; clearly indicating that it is necessary to build or adjust the retort to suit the character of the hydrocarbons, to say nothing of the nitrogen. Nor will laboratory methods, or any small retorts we know, do more than indicate to a minor degree the results

to be obtained in actual practice; laboratory results are usually maximum in quantity and poorer in quality than working results.

I am writing you this because we now have the actual proof of the correctness of the somewhat startling assumption about mass carbonization, but, inasmuch as we have accomplished today in an average of 100 minutes what usually takes 24 hours, I am sure the fact will be helpful to the industry and if for no other reason than that large tonnages that are so essential are easily dealt with, in other words, the old 5-ton retorts can be replaced by 50-ton units or larger and at far less cost per ton.

I have heard it said that it is quite easy to treat shale or any non-intumescens material. Perhaps it is, but no method of low-temperature distillation of intumescens shales (and there are some), bituminous coals, etc., has, so far as we know, on either side of the Atlantic, been yet accepted as an unmitigated success. Recent results, however, indicate with a considerable degree of certainty that a practical method of handling intumescens materials by low-temperature methods is within sight and without entirely disregarding the nitrogen content.

ARTHUR L. PEARSE.

Mining in Dutch Guiana

The Editor:

Sir—In your issue of January 1, I notice an article from a correspondent on mining in Dutch Guiana. Mr. Van Wagenen asks why it is that this country, where he states that nearly everything is favorable for successful gold mining, is neglected, and why Siberia is more attractive. He then asks if the reason is political, economical, or merely psychological.

Having been in both countries, I beg to differ with several of his statements, and offer the opinion that the main drawback to Dutch Guiana as a gold-mining region is economical. Perhaps he can tell me how to mine a two-foot vein averaging around \$2.50 in gold per ton, almost anywhere and make a commercially attractive profit. I do not know how to do it! And the long string of failures on exhibition down there rather bears me out.

Granted that the field is reasonably near the United States; is orderly politically; fairly well connected with the rest of the world by steamships and cables; it is not what I call healthy nor particularly attractive as an abode. There is plenty of malaria, as in all swampy tropical countries. Mining supplies can be bought there, largely imported, and the usual tropical foods are grown, but no one as yet has demonstrated any remarkable commercial gold deposits, unless the river Lawa placer operations can be so termed.

Labor is undoubtedly cheap, but it is not worth any more than you pay for it, and not to be compared with the better grade of Mexican labor in either efficiency or ability. And how could it be so, with no large underground mining operations in existence?

While there is no water to fight on the surface, except something like 80 inches of rainfall per year (!), how

long would that statement be true when some deep shafts were sunk and extensive underground workings opened up?

Regarding the Western mining man who has produced \$135,000 in gold, how much did that cost him, and what profit can he show for his heart-breaking labors? And just how many millions of tons of \$3.37 ore has he in sight, and what are the width of his veins?

Mining people will go to Dutch Guiana a lot quicker than they will go to Siberia these days, as soon as you bring real proof that large commercial propositions are available, but they will not go to mine erratic one and two foot veins of \$2.50 ore that are liable to give out at any moment. Those are 'one man' propositions.

A. R. ROGERS.

New York, January 10.

The Single-Jack in Western Australia

The Editor:

Sir—In your issue of December 18 Mr. West states that Mr. Hoover was the man who introduced the single-jack at Lawler's, W. A. For his information I may say that Paddy Lawler, Billy Gibson, Moses, Jack Wallace, and myself all used single-jacks at Lawler's before Hoover appeared on the eastern goldfields of W. A.; we were the discoverers of Lawler's and the locators of the Great Eastern, the True Blue, Donegal, and Lawler's Reward, comprising the East Murchison, sold to Bewick, Moreing & Co. through Mr. Dunsford and experted by George Armstrong. Hoover came a little later. Mr. West must have been an energetic young man to have peaked into every hole in Kalgoorlie in 1897; there was quite a number there at that time. Pat Hannan, the discoverer of Kalgoorlie, was a single-jacker on Parker's Range before he came to Coolgardie. Arthur Bailey and Bill Ford, the discoverers of Coolgardie, were both single-jackers in Queensland and other camps in the North-West; in fact, the single-jack was used from Gympie to Mount Morgan and from Mount Morgan to Kimberley and from Kimberley to Southern Cross before either Hoover or West saw the Antipodes; it was known as a 'gympie', taking its name from the place it was first introduced, in Australia. So much fuss about nothing. If you meet Mr. West, you will be able to tell him who first used the single-jack; it was the prospector. When you consider the nature of the country and the vast distances from the sources of supply, the reason is obvious.

Sampling in a Mill

The Editor:

Sir—The following may be of interest to Messrs. Eye and Dodd, authors of the recent article on 'Milling Practice at the Benguet Consolidated Mine'.

In their interesting article they mention that "sam-

pling the discharge of the mortars—with correction for the estimated amount of value dissolved in stamping—gave results not close enough to be dependable".

The head sample at the Rochester Silver Corporation mill is arrived at by the following procedure:

The ore passes through 10 stamps to Dorr classifiers and tube-mills in closed circuit. At the discharge of each classifier a pulp-sample is taken over a period of 24 hours, at half-hour intervals. The entire sample is saved. After being mixed well, the following samples are removed from the pail:

One for moisture to determine the ratio of solution to ore.

One for solution value.

One for washed-pulp value.

A sample of the solution entering the batteries is taken over a 24-hour period.

The calculation is:

Let a be assay-value of battery solution.

b be assay-value of classifier solution

c be assay-value of washed pulp.

d be ratio of solution to ore in sample.

then $(b - a) d + c =$ heads.

In the five years that this sample has been used it has been 6% to 8% lower than bullion plus contents of tailing.

The following factors probably affect the accuracy of this method:

The usual inaccuracy of sampling by mill-men.

Moisture in the ore from the mine.

Tube-mill pebble tonnage.

Evaporation.

W. G. EMMINGER.

Rochester, Nevada, December 15, 1920.

LEAD PRODUCTION during 1920 is summarized as follows: The production of primary domestic de-silverized lead was about 215,000 tons, of soft lead 189,000, and of de-silverized soft lead 70,000 tons, making a total output from domestic ores of about 474,000 tons of refined lead, compared with 424,433 tons in 1919, made up of 208,751 tons of de-silverized lead, 147,744 tons of soft lead, and 67,938 tons of de-silverized soft lead. The output of lead smelted and refined from foreign ore and bullion was about 64,000 tons, compared with 57,787 tons in 1919. The total lead smelted or refined in the United States was thus about 538,000 tons, compared with 482,220 tons in 1919. The production of antimonial lead was nearly 12,000 tons, against 13,874 tons in 1919. The exports of lead of foreign origin were about 22,500 tons and of lead of domestic origin 3000 tons, compared with 42,912 tons and 10,510 tons, respectively, in 1919, a decline of nearly 28,000 tons in the total exports. The imports of refined pig-lead, which for the years 1916 to 1919 inclusive had been a little over 5000 tons per year, jumped to about 34,000 tons. Up to the end of November, 9425 tons of refined lead had come in from Mexico, 1680 tons from France, and 12,978 tons from England. Some trans-shipped Spanish and Australian lead is included in these quantities.—U. S. Geological Survey.

DALY-JUDGE MINE, PARK CITY, UTAH

Metallurgical Operations of the Judge Mining & Smelting Company

By Arthur B. Parsons

The Judge Mining & Smelting Co. is a consolidation of the Snake Creek Mining & Tunnel Co. and the old Daly-Judge company. It owns a modern 500-ton concentrator situated near the portal of the principal adit of the mine and an electrolytic-zinc plant with a capacity of 10 tons of high-grade zinc ingots per day. The mine and mill are just above the town of Park City, Utah, whereas the electrolytic plant is situated on a railroad spur some distance below the town, and about $2\frac{1}{2}$ miles from the concentrator. Recently the same interests have acquired control of the Daly, Daly West, and Park-Utah mines, and arrangements have been made whereby all are operated under a single management. The workings of the Daly and Daly West mines are connected with those of the Judge, and all the milling ore at the present time is hauled $1\frac{1}{2}$ miles or more through the Judge adit to the concentrator. Ore of shipping grade is routed through No. 1 drain tunnel directly to the railway loading-station.

The ores are both carbonate and sulphide, but the principal valuable minerals are galena, sphalerite, and pyrite. Only small amounts of copper and gold are present, but the silver content is important, ranging from 10 to 30 oz. per ton. The gangue is silicious, being principally quartzite. Two classes of ore are mined; one for direct shipment to the smelter in the Salt Lake valley and the other for local treatment. Typical average assays of the two grades follow:

	Silver, oz.	Gold, oz.	Lead, %	Copper, %	Zinc, %	Iron, %
Shipping-ore	30.0	0.025	16.5	1.25	8.25	7.75
Concentrating-ore	14.5	0.02	10.5	0.75	12.5	5.0

Two concentrates are made in the mill, namely, a lead

concentrate, reasonably low in zinc, which is shipped to the smelter, and a zinc concentrate, containing considerable lead, for roasting, leaching, and precipitating at the electrolytic plant. The ratio of concentration for lead is 4.5:1; for combined lead and zinc concentrate it is 3:1. Typical analyses of these two concentrates follow:

	Silver, oz.	Gold, oz.	Lead, %	Copper, %	Zinc, %	Iron, %
Lead concentrate	24.5	0.04	31.5	0.6	8.9	19.5
Zinc concentrate	15.0	0.02	4.5	..	39.6	6.5

THE CONCENTRATOR. The feature of the concentration is the separation of the intimately mixed lead and zinc minerals. Jigs, tables, and flotation-cells are used in the process, in rather intricate combination, the flow-sheet being complicated because of the re-treatment of flotation products on Wilfley tables. Omitting many of the details, the treatment may be described briefly as follows: After being crushed in two sets of 15 by 36-in. Allis-Chalmers slow-speed rolls, with an intermediate trommel, the ore is sized in a series of trommels with 3, 4, and 8-mesh screens preparatory to concentration in Harz jigs, equipped with Missouri plungers. The undersize from the last trommel is classified hydraulically for finer jigging. All these jigs make a finished lead concentrate, a middling, and a tailing to be discarded. The middling from the primary jigs is re-ground in a $4\frac{1}{2}$ by 6-ft. Marcy ball-mill fed with 4-in. manganoid steel balls, and a product passing an 8-mesh trommel, but oversize on a 22-mesh Callow screen, is separated to feed two zinc-jigs. These make a product ready for the electrolytic plant. Instead of the drag, or rake-classifier, generally used, a trommel with $\frac{1}{8}$ -in. screen, in closed circuit with the

Marcy mill, gives large capacity and minimizes the quantity of slime produced in grinding.

Richards-Janney classifiers and a Richards free-settling classifier are used to prepare the undersize from the 8-mesh Callow screens for Wilfley tables. The usual intermittent discharge from the Richards-Janney classifiers has been discontinued with a view to providing a more uniform table-feed; so operated, it has given equally good results as to sizing. The tables make both a lead and a zinc concentrate, a middling for re-dressing, and a tailing. The slime overflowing from the classifiers and that from sundry Callow cones is collected in a three-deck 36-ft. Dorr tank where it is thickened preliminary to flotation treatment. The plow-arms are rotated by a 5-hp. individual motor connected through a D. O. James speed-reducer by means of which 1800 revolutions is diminished to 64.

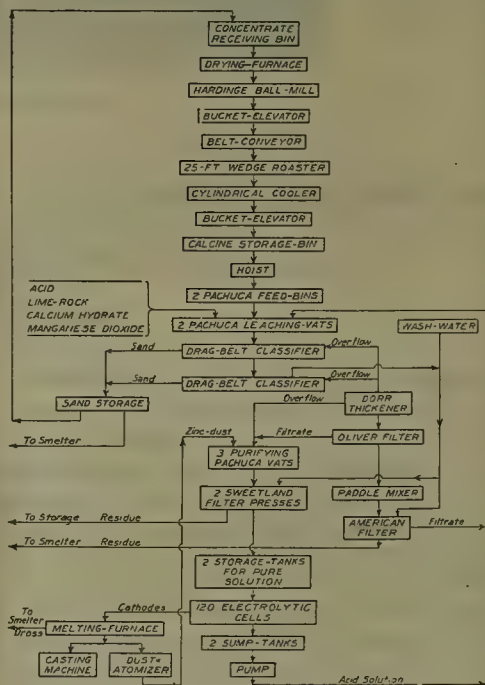

FLOTATION. Pneumatic cells are used. No differential or preferential flotation is attempted, as experimental work has not been sufficiently encouraging to warrant the attempt, especially in view of the fact that the lead in the zinc concentrate is recovered from the leached residue from the electrolytic plant. The status of flotation litigation is a deterrent to the use of the process. Indeed, I am told that the company may discontinue the use of flotation entirely and substitute another method of slime treatment. Ninety per cent of the flotation concentrate is re-treated on Wilfley tables where the zinc and lead are separated. Such flotation concentrate as is not tabled, and the overflow from the drags is pumped to a small tank, equipped with Dorr thickening-rakes, the underflow from which goes to an 8-ft. Portland filter with a 3-ft. face. The filter dewateres the concentrated slime to about 25% moisture. The jig and table concentrates are dewatered by means of belt-drags of various sizes and with slopes of varying inclination, the maximum being 45°. The rakes are composed of angle-iron bent so as to travel in a vertical position, and are fitted with replaceable shoes, consisting of flat strips that are bolted to the projecting part of the angle. These shoes have four or five notches $\frac{1}{4}$ in. wide in the edge next the plane upon which they drag, and alternate ones are displaced sidewise in one direction a distance of half an inch. These two details of construction are uncommon; the purpose is to assist the flow of draining water and thereby effect a more complete dewatering of the concentrate, the moisture in the finished product ranging from 12 to 16%.

The total recovery in the concentrator is not exceptionally high, especially with respect to the zinc, but an adequate supply of concentrate for the electrolytic plant is made, and, for various reasons, it is deemed inadvisable to make any radical alteration in the scheme of treatment at the present time.

The railroad does not reach the mine and concentrator; accordingly the concentrates are hauled by team either to Park City, to be loaded on railway-cars, or beyond to the receiving-bins at the zinc-plant. The operations there will now be described.

TREATMENT OF ZINC CONCENTRATE. The process consists of a number of consecutive operations, namely, drying and grinding the concentrate, roasting, leaching by agitation, filtration, purification of the solution, clarifying, electrolytic precipitation of the zinc, and melting and casting into bars for shipment. The sequence of treatment is indicated on the accompanying flow-sheet.

Until recently the procedure had been to put only the jig-concentrate through the dryer and ball-mill, while the table and flotation products were handled separately up to the point where they were charged in raw form on the top, or drying, hearth of the roaster. In October, when I was at the plant, all the concentrate was being mixed in the receiving-bin that feeds the dryer. The

FLOW-SHEET OF ZINC REFINERY

additional grinding of the table-product, 20% of which is plus 60-mesh, improves the roasting and likewise the extraction in the leaching Pachucas. The fineness of the table-concentrate produced will govern future practice in this regard. There is also mixed with the raw concentrate approximately 3% by weight of the coarse leached residue. There is still 20% zinc in this product, some of which is freed by further grinding and a second leaching; but the principal virtue is in diluting the sulphide to some extent, thereby hindering the tendency of the calcine in the roaster to fuse, as well as keeping the charge cool and porous.

ROASTING. A belt-conveyor carries the mixture to the hopper feeding a revolving coal-fired dryer in which the moisture content is reduced from 12 to 15% down to 1 or 2%, previous to being ground in a Hardinge ball-mill. While no attempt is made to screen and return any over-

UPPER HEARTH OF ROASTER SHOWING BELT-FEEDER

SWEETLAND FILTER WITH WIDE-LEAF SPACING, AS USED IN THE ZINC PLANT

size to this ball-mill, practically all the product will pass a 60-mesh screen. The ground material is elevated to a bin from which it is fed by belt-conveyor to the drying-hearth of a 25-ft. Wedge roaster, making one revolution in from five to eight minutes. This rate can be altered by means of a Reeves variable-speed transmission, but since the purpose is to approach a dead roast as nearly as possible the furnace has always been operated at $\frac{1}{2}$ r.p.m. A Wilson-Maule pyrometer, the recording mechanism of which may be connected with any hearth by means of a series of wires connected at a central switch-box, is read every four hours, typical readings under normal condition being as follows:

Hearth	Degrees Centigrade
1 (or drying).....	280
2	600
3	500
4	550
5	650
6	660
7	450

While the ideal is an isothermal roast at 650°, in actual operation the second, fifth, and sixth floors are hotter than the others, and the furnace-arms on these hearths are accordingly cooled with water, instead of air. Cooling-air is circulated through the arms on the remaining hearths by means of a No. 9 centrifugal fan made by the Buffalo Forge Co. With the usual feed, 14 or 15 hours is consumed in the passage of a given particle of ore through the furnace, while the sulphur content of the charge is reduced from approximately 30% to 2% of insoluble, or 'sulphide', sulphur. The roaster is fired with coal, the heat entering the furnace at the sixth hearth, thus permitting the seventh or bottom hearth to serve as a cooler, as indicated in the table of hearth-temperatures. The calcine then passes through a 6-in. iron pipe to a 5 by 16-ft. cylindrical cooler. This consists of an iron tube, with axial feed and discharge-openings, revolving in a bath of circulating water. Spiral screws convey the calcine through the dryer.

LEACHING. The cooled material is conveyed to a 400-ton storage-bin and is thence hoisted to three separate bins that in turn feed either of three 22 by 10-ft. Pachuca agitators in which the leaching takes place. The central lift-column of these agitators is square, made of fitted two-inch plank. At vertical intervals of two feet are collars of 2 by 4-in. material fastened together with wooden pins that tighten as they are driven. This column was designed at the plant; it is cheap, serviceable, and has proved durable in spite of severe service. A large volume of air is used for agitation, and it is necessary to put a horizontal baffle over the top of the lift-column to prevent violent splashing. The term 'leaching' is perhaps not accurately applied to the operation, and is misleading in so far as there is no percolation. The solution and calcine are agitated and the pulp dewatered by an Oliver filter. The process is intermittent, the period of a cycle being six to eight hours. First, 33 tons of electrolyte that has passed through the cells is run into the agitator from the storage-vat to which it is periodically pumped from the sump below. Into this solution, which

should contain 45 gm. of sulphuric acid per litre, is introduced sufficient calcine to consume all but a small proportion of the free acid; less than one gramme, as determined by titration, generally remains after the addition and agitation of approximately five tons of calcine. To finally neutralize, 100 lb. of crushed limestone for each gramme-per-litre of free acid is added, together with 125 lb. of calcium hydrate. Most of the silica that may have been dissolved during the acid treatment is precipitated in gelatinous form at this stage of the process, although some further removal is accomplished in the subsequent purification of the filtrate with zinc-dust. It is then only necessary to oxidize the ferrous sulphate to

DETAILS OF ANODE AND CATHODE

ferrie sulphate in order to precipitate the iron and antimony.

This is effected partly by the air introduced in agitation and partly by the addition of manganese di-oxide, of which about 15 lb. per charge is required. The operation is similar to the method of removing arsenic at the Anaconda Copper Co.'s plant at Great Falls. There is a minute quantity of arsenic in the Judge ore, but it disappears in the course of roasting, and only antimony remains to be precipitated. The original plan was to oxidize with potassium permanganate, but inability to secure an adequate supply of this reagent resulted in the selection of manganese di-oxide as a substitute. It is not satisfactory, but, being a by-product of the cells, it is always available and serves the purpose. The objection to its use is inferior work in the cells, consequent to in-

ELECTROLYTIC CELLS IN THE ZINC REFINERY

complete purification. This will be mentioned again.

To complete the cycle, the charge is pumped through wooden pipes to a 4-ft. Esperanza drag-classifier, with wooden rakes, where the coarse leached sand is removed with about 18% moisture. Recently a second smaller drag has been installed to wash this sand with water and thus reduce the loss of dissolved zinc by replacement of a part of the rich zinc solution.

FILTERING. The overflow from both drags goes to a 30 by 12-ft. tank fitted with a lead-covered shaft and Dorr rakes of bronze. The pulp, thickened to a consistence of 3:1, water:solid, goes to a specially made 8-ft. Oliver filter. The spokes and rims of the drum are made of wood, the wires and screens are of copper, and the pipes are of lead, while the cover consists of a woolen blanket beneath a special twill-canvas that lasts two months. The hopper itself is made of steel plate but is lined with lead. This filter removes only two-thirds of the solution, the cake containing about 50% moisture; to further reduce the loss of zinc sulphate an American continuous disc-filter has lately been installed. The Oliver filter-cake is mixed with water in a locally built paddle-agitator, and pumped to a second Dorr thickener, the thickened pulp from which goes to the American filter. The tank and frames are of redwood and the three 6-ft. discs duplicate the results of the Oliver. The Oliver makes a cake $\frac{3}{4}$ in. thick as against $\frac{1}{2}$ in. for the American, but neither is able to dry to less than 45% moisture. A 14 by 18-in. vacuum-pump, lined with bronze and made by the Doak Gas Engine Works operates both filters through individual wooden receivers, by the dry-vacuum system. Nineteen inches of vacuum is maintained.

Typical analyses of the two residual products are as follows:

	Zinc, %	Copper, %	Lead, %	Silver, oz.
Classifier sand	20.5	0.85	4.8	20.0
American-filter cake	12.8	0.85	7.1	19.5

The figures giving the zinc content indicate the more effectual extraction of the zinc in the finer material. Only 20% of the residue is sand, however, and as mentioned before part of this is returned to the head of the mill for re-treatment.

PURIFICATION. The next step is the purification of the overflow from the thickener and the filtrate from the Oliver filter, that is, the removal of the copper and cadmium together with any remaining antimony and silica before the solution is ready for the electrolytic cells. This is done by treating charges intermittently in any one of three 10 by 15-ft. Pachuca agitators, equipped with lift-columns of wood similar to those in the leaching agitator. Brisk agitation for 30 minutes after the addition of zinc-dust, in the proportion of three pounds of dust per ton of solution, suffices for this purpose. Two grades of zinc-dust are used separately; four-sevenths of the total is zinc coarser than 60-mesh and grading up to 8-mesh, while the remaining three-sevenths has passed 60-mesh. It has been found that the coarse zinc precipitates the copper readily but does not replace the cadmium, and, moreover, that the finer-sized material precipitates the cadmium more efficiently if the copper has already been removed. It is for this reason that the two grades are prepared separately and added successively, although the precise reasons for this behavior are not known. The dust is prepared, in the furnace-room

where the stripped zinc-sheets are melted, by a process devised at the plant. Molten zinc is allowed to flow in a small stream into a current of compressed air issuing at a pressure of 100 lb. from a special nozzle made of a one-inch pipe-cap. The zinc is effectually 'atomized'; it is collected in a large galvanized chamber at the hoppers bottom of which is a conveyor, and only requires screening to be ready for use in the purification process.

The precipitate of copper and cadmium is removed by passing the solution through two 3-ft. Sweetland disc filter-presses, each having 36 leaves. The copper having been precipitated, and the solution at this stage being neutral, the Sweetland presses are of standard construction, that is, they do not require parts of acid-proof material. They are cleaned daily and give satisfaction. The cake from the Sweetland presses, containing 50% zinc, and approximately 5% each of copper and cadmium, is at present stored pending the perfecting of a method of recovering the metals economically. Experimental work indicates the development of a successful scheme. The clarified solution goes to two storage tanks, each 18 by 21 ft., from which it is drawn as required for the precipitating-cells.

ELECTROLYTIC PRECIPITATION. As originally built, the electrolytic department comprised 120 cells in two groups of 60. Each cell contained twelve aluminum discs, 5 ft. diam., mounted on a slowly rotating shaft, alternating with lead anodes supported independently of the shaft. While it is possible that this arrangement might have proved successful had the original scheme of purification with permanganate been feasible, the revolving discs were replaced after some months of operation by the present stationary equipment with rectangular anodes and cathodes. The detrimental effects of incomplete purification were magnified by the rotating discs and difficulty resulted from warped plates and poor contact of the cathodes. The grade of the zinc was above 99.9%, but the current-efficiency was only 50%, as against 80% now regularly being obtained. Though theoretically good, the discs appear to be too delicate for practical use.

The present plant contains two sections, each composed of 60 cells containing 19 lead anodes and 18 aluminum cathodes. The containing-vats are 7 ft. long, 3 ft. wide, and 4½ ft. deep, arranged in rows of 10, there being six double rows across the width of the room. An aisle 10 ft. wide affords working-space between the double rows. Three of these double rows comprise an electrical unit, while for the purpose of introducing the electrolyte the rows are divided into series or cascades of five cells, there being a difference of three inches between the elevation of successive cells. For convenience, there is also a wide aisle going across the room between the two groups of cascades.

Both anode and cathode bus-bars are on the side of the cells next the working-aisle, the anode bus being inside and ¼ in. lower than the cathode. One end of the anode and cathode supporting-rods rest directly on the copper surface of the bus-bar while the opposite end bears on a wooden strip placed on the inner side of the vat. They

are made of rolled copper; are supported independently of the vats by wooden posts, with heavy glass-plate insulators; and taper from a maximum cross-section of 4 by 1½ in. to a minimum of ¼ by 1½ in. as the point of minimum current is approached. The tapering dimension is vertical. This saves copper without impairing in any way the serviceability of the bus. Sixty cells are connected in series, the connection being made from the cathode to the anode bus by means of a copper plate, 4 by 7 in. and ⅝ in. thick, joined by means of six ½-in. bolts.

The anodes are made of cast-lead sheets, ¼ in. thick, supported at the top by means of a steel rod, one inch square, about which the sheet is wrapped. In order to effect good electrical contact a tinned copper wire, size 00, is burned into the lead as indicated in the accompanying sketch, and carried along the top of the steel bar to a hole near the end. It passes through this hole and is beaded to present a greater surface to the bus-bar. An attempt to make electrical connection by sweating the lead to the steel was a failure.

The construction of the cathodes is likewise shown. These are made of the best obtainable sheet-aluminum ⅜ in. thick, supported by two 1½ by ⅜-in. strips of copper, riveted together with the upper edge of the aluminum sheet between them. The two small iron lugs at either side of the aluminum sheet serve as a means for lifting the cathodes from the vat and carrying them to the stripping-floor.

The normal area per cathode exposed to the action of the electrolyte is 68 by 22 in. while the corresponding anode-area is 66 by 21 in., which gives 203.5 and 173.25 sq. ft. as the respective areas for an entire cell.

The practical measure of the results obtained in the cells is the net current-efficiency, that is, the amount of zinc actually precipitated per unit of electric energy as compared with the ideal quantity that should be precipitated. The rate of deposition on the cathode plate theoretically is dependent upon the current-density. There is, however, a continuous re-solution of deposited zinc by the cell-solution that varies with the chemical and physical condition of the electrolyte as well as with that of the zinc itself. The character of the deposit is affected largely by the kind and quantity of impurities remaining in the filtered solution from the leaching plant; in fact, it is fair to say that the essence of the entire process is adequate purification. The compactness of the deposited zinc is, however, affected by the rate of deposition; this in turn has a bearing on the rate of re-solution, and accordingly a standard current-density has been determined that will balance the various factors to the best advantage. Under the conditions in this plant 27 amperes per square foot of cathode has been found to give the best results. Typical analyses of the electrolyte as it enters and as it leaves the cells follow. The figures represent grammes per litre.

	Sulphuric		Cadmium		Copper	Antimony	Manganese
	Zinc	acid					
Influent solution	57	0.2	0.003	0.0006	0.0010	0.415	
Effluent solution	20	45.0	Trace	0.0002	0.0009	0.035	

These figures call attention to a number of facts: It is

desirable that the effluent solution contain approximately 20 gm. of zinc, for the reason that if the electrolyte is impoverished below that point the cells become 'starved' and the re-dissolving action is accelerated. The same result is found when the free sulphuric acid in the effluent electrolyte exceeds 45 gm. Solution of the strength shown establishes an economical balance and these strengths are maintained by the regulation of the rate of flow through the cells. Normally, solution is added in the first and third cells in the cascade of five, although the pipe-connections enable the introduction of solution at any cell. It is found advisable to flush the cells occasionally, thus increasing the zinc content of the solution in the lower part of the cascade and thereby stimulating electrolysis.

The solution analyses reveal the fact that the cadmium, copper, and manganese are, to a great extent, precipitated in the cells while the antimony remains in the effluent solution. Manganese is one element that does not appear to have any bad effect on electrolysis. While the chemical reactions are not definitely known the actual result of the presence of manganese is an accumulation of manganese di-oxide at the anode surface. At intervals the anodes are removed singly from the vat and the accumulation scraped off, thereby exposing the fresh surface and increasing the current-efficiency. The scrapings are returned for use in the leaching-vats.

On account of the scarcity of water the first unit of the cells was operated without any provision for cooling the electrolyte. The temperature naturally became excessive and the re-solution of zinc increased prohibitively and it was apparent that the electrolyte in the cells must be cooled. To provide for the re-use of the cooling-water an outdoor spray system consisting of 18 vertical nozzles from pipes supported over a concreted pond, 50 by 75 ft., was constructed. This scheme is inexpensive and affords an adequate supply of circulating water to regulate the temperature in the cells even with the limited amount of fresh water obtainable. Each vat is fitted with a coil made of 45 ft. of lead pipe through which the cooling-water passes. A valve for each vat permits the regulation of the temperature of the units independently.

The cathodes are stripped by hand once in 24 hours, nests of six being removed from the vat by means of a one-ton chain-block to which is attached a frame made of angle-iron. This frame is designed to engage the iron lugs that are riveted into the supporting-rods of the cathodes. An overhead trolley serves to convey the chain-blocks and their load to the lower end of the vat-room where the stripping is done. The sheets of zinc are about $\frac{1}{8}$ in. thick and are comparatively compact and uniform, although there are occasional boils, blisters, and rough spots. To assist in stripping and to prevent warping and irregular wearing along the edges of the aluminum sheets, wooden strips, 36 in. long and $\frac{3}{4}$ in. square, with a narrow groove $\frac{3}{8}$ in. deep along one edge, are fitted tightly over each side of the cathode. These are removed by the employees who do the stripping; the sheets of zinc are then loosened and peeled off, after which the alum-

inum is swabbed with a wash of dilute sulphuric acid before being returned to the vat. This wash has been highly effective in improving the character of the zinc deposit, the reason probably being that the cleaned surface is in good condition to receive the first particles precipitated. The wooden strips are of course replaced.

MELTING THE ZINC. The stripped zinc sheets are carried by wheelbarrow to a small coal-fired reverberatory melting-furnace, with a hearth 7 by 12 ft., in which the temperature is maintained at from 600 to 700°C. Here the dross of zinc oxide is skimmed after which the zinc is ladled and cast into 50-lb. ingots, marked 'Judge Electric', ready for shipment. These ingots are exceptionally high-grade, the analysis showing 99.94% zinc with small amounts of lead, cadmium, and iron. The dross now amounts to 15% of the gross weight of the cathodes, but improvement in the electrolytic department is expected to reduce this proportion materially, although the product contains 89% zinc and is practically free of lead so that there is a ready market for it.

The electrical equipment was furnished by the General Electric Co., the principal machines being two units, each composed of one 1750-hp. synchronous motor, Type AT 1, operating at 720 r.p.m. from a 2200-volt, 3-phase line, and one direct-current generator, Type MCF, capable of producing 5000 amperes at 250 volts. Imperfect conditions in the cells at times throw an excessive load on these machines, so that it has been found necessary to provide means for mechanical cooling. For this purpose a Sturtevant blower, size 10, drawing air through a 6 by 10-ft., type H, washer was installed. The cooled air is forced through large sheet-iron pipes to the vicinity of the windings of the motors and generators. Switch-board arrangements provide for the use of either motor-generator set to supply either of the two cell-sections independently. Power reaches the plant over a 44,000-volt transmission line and is stepped-down to 2300 volts by four 1000-kva. type H oil transformers. Sundry motors about the plant operated at 440 volts, with appropriate transformers, provide this current.

More than 20% of the cost of operating the plant is the item of power; the peculiar position of the company with respect to its resources in this particular was one of the factors that counted in the decision to build the plant. The Judge company is the owner of the Snake Creek Mining & Tunnel Co., which developed a large flow of water when driving the Snake Creek tunnel. This water is utilized by the Utah Power & Light Co., which in turn supplies power to the Judge company from any one of three independent sources, with which its transmission lines connect. This assures a constant supply of power, but does not entail the operation of a generating plant on the part of the mining company.

O. N. Friendly, general superintendent for the Judge companies at Park City, and John T. Ellsworth, superintendent of the zinc-plant, afforded me every opportunity for getting data on the operations of the plant, and I am indebted to George W. Lambourne, general manager, for permission to publish this article.

Educating Versus Drop-Forging

By Will H. Coghill

The young man who enters the mining school "knows what he wants", but does he know what he needs? The answer is yes, and no. On the basis of appended data, those entering the mining schools of Columbia University and Massachusetts Technology do know what they need, and those entering certain three isolated Western mining schools do not know what they need.

Of the five schools mentioned, a comparison of the number of graduates whose names appear in 'Who's Who in America' is striking.

Graduates Honored by 'Who's Who'

Designation of school	Number of graduates 1882-1905	Number of graduates in 'Who's Who', 1913-1914	Percentage honored
Columbia	312	26	8.3
Mass. Technical	183	8	4.4
Isolated No. 1.....	245	2	0.8
Isolated No. 2.....	138	1	0.7
Isolated No. 3.....	256	0	0.0

Look at Columbia's honored number: 26 out of 312. Then, again, look at the factory output of No. 1, 2, and 3; the former graduates educated to meet the ever-changing conditions of life; the latter drop-forged, as they want to be.

This is not a plea to have Western schools closed, but it is to urge that we look to the Eastern educators as a guide; they were groping with the problem of education before the West was known. Why not profit by what they have learned?

A boy stated to me a few days ago that he left the university because he was required to take language, and explained that he had two years of English in the high-school. "And that is enough", said he. He is now being hammered in the practical forge to be shaped into an assayer, surveyor, miner, metallurgist, or geologist. Will he be able to meet the conditions of the mining engineering profession twenty years from now? The chances are against him. Those who can look back that far to their school-days know that the "practical stuff" hammered in by the professors is now mere chaff.

The enrollment of the Columbia mining school is small as compared with the Western schools, because it requires three years of college training for entrance. The educators believe that this is best. Contrast this curriculum with the self-laudatory comments appearing in the technical press when a Western school "introduces a course in English".

The factory keeps its fingers on the pulse of the industrial world and supplies the commodities required tomorrow. When these are consumed they are forgotten and a new output is forthcoming. But the output of a school cannot be forgotten. The school deals with souls, not commodities to be consumed and replaced by the demands of rushing time. When the high-school graduate enters a mining school and, finding that the oil geologist is the popular product, requests that he be 'pegged' with

the geologists, it puts the selection of a course of study too much on the same basis as the ordering of a dinner. It is as if the waiter were saying, "The cutlets are very fine today, sir", whereupon the boy takes the hint and orders his menu accordingly. Such a system of 'ordering' in our schools, when the 'digestive organs' are not sufficiently developed to stand the 'cramming', will bring forth an output that will live to shame the 'factory'. The older educational institutions have found that it is best to require a period of development through college training before allowing the student "to place his order". Should we not profit by their experience? If we do not, our products will lack the solid foundation and basic principles necessary to keep them up with the procession.

The teachers in the isolated mining school are placed in an odious position when they are required to be practical while placed between four walls, floor, and ceiling, and the student is losing the opportunity to get the foundational work upon which a superstructure can be built or altered or re-built, as occasion shall arise and experience shall dictate.

I plead as a victim to the drop-forge system of 'education', which I would see discarded.

THE ZINC INDUSTRY in 1920 in foreign countries is briefly reviewed by the U. S. Geological Survey. Of the European zinc-producing centres, Belgium and Upper Silesia seem to be in the best condition. Belgium started the year with a smelter output of about 4500 tons monthly, which it brought up by the middle of the year to about 8000 tons. After that the output remained about stationary, so that the total production for the year was probably about 90,000 short tons. Reports near the end of the year indicate that the output is slackening and considerable stocks are on hand. The total stocks in Europe are thought to amount to 100,000 tons. Belgian smelters have recently contracted for a supply of Australian zinc concentrates. The zinc output of smelters in Upper Silesia in 1919 was 81,596 tons, equal to about 60% of the production in 1918. Reports for the first half of 1920 indicate a little larger production than in 1919, the output for the six months being 49,643 tons. The zinc industry in other European countries and in Japan is reported at a low ebb. Perhaps the most noteworthy happening in the zinc industry during the year was the acquisition of the Mount Read and Roseberry mines, Tasmania, by the Electrolytic Zinc Co. of Australasia, by which the company gains immense reserves of ore. The enlargement of the electrolytic zinc plant at Ridsen, near Hobart, Tasmania, continues, a zinc-rolling mill and a zinc-oxide plant having been completed.

NICKEL is produced in Guiana and New Caledonia, the latter colony being the largest producer of nickel in the world, with an output of 100,000 tons. New Caledonia is, in fact, one of the richest of the French colonies, with valuable deposits not only of nickel but of lead, zinc, silver, manganese, antimony, mercury, and a small amount of gold.

The Economic Aspect of Economic Geology

By Charles A. Porter

Economic geology is commonly viewed purely as a branch of physical science. As the name indicates, however, there is an economic element, and when this latter is examined, and its influence investigated, it is found to be a factor that must be considered in order to form a complete conception of what economic geology is. Examination will show there are striking differences between the economic and physical sides of the subject. It should be especially noted that the physical factors are, for all practical purposes, completed, and are therefore fixed and invariable in their nature; while the economic factors are still active, and display an ever variable and changeable nature. Indeed, it is in the economic influences that we find the factors that determine what shall, and what shall not, be economic geology.

In order to realize fully the separateness of the physical and economic elements, one has but to consider the common segregations of minerals that exist today as deposits of copper, gold, or silver, and to realize that they have lain practically unchanged for untold ages, extending back to a time long before man had yet reached a stage that could be called man, and before he had yet any idea that the metals could be utilized. Such a conception will give us a condition in which the physical agencies had been exercised to the full. They had, to a high degree, concentrated those metals that today are economically valuable. The physical processes were as complete as at present; but in the absence of value, it is indeed difficult to say that there was such a thing as an ore deposit. An extreme concentration of quartz under the same conditions would as truly have been so termed. At the time such deposits were formed, it may be said, they were equally 'useless'. That is, they lacked the 'utility' which has been recognized by the economist as essential to the existence of value. There were no minds that, after the physical processes were completed, could take the metaliferous concentrations and, through intricate processes, fit them to the complicated needs of the independent purposive actions of the highly evolved organism we know as man. Without these minds, and the needs of mankind, and also the realization of these needs, there was simply a mass of relatively homogeneous matter, and 'ore' could not exist until the coming of these phenomena which are incidental to the psychozoic age. Economics and economic value were non-existent; as the utilities that form the foundation of economic worth were yet to be brought into being.

Recent instances of these conditions are found in the cases of tungsten and molybdenum. Before the rise of modern technology, tungsten was of but little, if any, use. With the growth of the steel industry, and a knowledge of the attributes of tungsten-steel alloys, tungsten has developed a measure of utility; and what were once

deposits that no one a century ago would have called 'ore', now properly received that appellation. Still more modern is the case of molybdenum. This metal has been of but trifling economic value until recent years. Today its price is regularly quoted, and its use seems to be steadily increasing. These deposits have ceased to be merely subjects of scientific study or of simple curiosity, and in a few decades, through processes entirely unrelated to the cosmic processes that resulted in their formation, have become deposits of economic importance.

Economic value, at least as far as ore is concerned, being but a concept of the human mind, it is to be expected that it should be anything but of a fixed and stable nature. Economic value results from a mental condition that selects particular segregations, showing a 'preference' for this or that mineral. In the last analysis, value is dependent on desire, as well as utility, and the ever-shifting and insubstantial nature of these factors cannot be better expressed than in the words of a French economist: "As a shadow follows a butterfly from one flower to another, so utility accompanies desire, and abides only where desire rests." Hence we may see how the instability of the economic factor of geology stands in marked contrast with the completed physical aspects. And with the recognition of the economic factor and its influence in determining what shall and what shall not be 'ore', we must see that the science of geology, even though it attain, on its physical side, to the precision and perfection of mathematics, must always be subject to the modification of the independent and variable economic element. The latter being an influence of extreme complexity, changing with the general demand for the mineral contained in the deposit, with the difficulty of its exploitation and the energy of those who are in a position to exploit it, it will vary in proportion as substitutes are developed, or exhausted: Indeed, it will vary with the development of the science itself. It is obvious, if economic geology should attain to such perfection that any adept could, by a superficial examination, infallibly state that an orebody of certain dimensions, character, and value existed at a particular point underground, that many such deposits would readily be found, and the economic value of each certainly would fall. Hence we see that economic geology, by its own successful use, would ultimately alter the economic status of existing orebodies.

In this economic aspect and its variability, we find one of the great limitations of the geologist. He may be master of the physical processes, and such factors in any given deposit may be fully understood by him. He may rise to any degree of perfection in his prognostications, but his powers are limited to the location, volume, and

mineral composition of the deposit. He may say today: "It is not ore", and tomorrow the shadow of the butterfly may fall upon the deposit. Once pure science enters into the hurly-burly of the business world, it finds itself in a never-ending series of compromises. In the case of economic geology, where in the last analysis, physical results are influenced by the desires and wants of the masses of humanity, the hard and fast facts of nature are modified in their effects by ever-changing circumstances that vary with the mental states of mankind. Fires, floods, wars, whims, fads, all may contribute. It is said that in the middle of the seventeenth century, a craze for tulips obsessed the Hollanders. At that time, this particular flower outstripped the precious metals in value. One root brought "four fat beef, eight pigs, twelve sheep, ten-hundred weight of cheese, two tuns of wine, one full attire (which probably means a suit of clothes), one cup of silver, a great quantity of wheat, and other provisions to the value of 25,000 florins". It is obvious that a fad for silver, of but a fraction of the intensity of the tulip craze, would raise many now worthless rocks to the status of 'ore'.

In the main, however, there is more or less regularity to the desires of man. They are, therefore, influenced greatly by the supply, and as desire is satisfied, the demand diminishes. Hence the economic geologist should realize that the supply of ore deposits finds its limitations precisely as shoe-factories do. A few only can be of pre-eminent success, a great many more will be mediocre, and a large class will just exist in the marginal region that economic forces have decreed lie just above that vast region occupied by economically worthless substances.

From the foregoing it should be seen that the selective action of mankind is the determining factor in what is, and what is not, 'ore'. And that the conception of 'ore' is human, and perhaps transient in the evolution of the cosmos. Should mankind ever attain to the transmutation of the elements, it may not be improbable that the metals can be produced more cheaply than can be done from the richest deposits. This is, of course, the alchemist's dream; but the study of radio-activity has again brought us back to first principles, and the transformation of radium into thorium and helium, and the practical certainty that lead is a radium residue, may well disturb our beliefs that the elements have always been fixed. Should transmutation become a fact, the conception of 'ore' will disappear, and a builder of the future may yet toss pieces of quartz heavy with gold and silver into the concrete along with the rest of the broken stone.

PETROLEUM always occurs as a liquid. Its more volatile parts may be taken into the air by evaporation or into dry clays by absorption, but the solid or semi-solid substance that remains is not called petroleum, but is known as asphalt, albertite, grahamite, or ozokerite, or by the more general term bitumen. Although all petroleum is liquid, they differ in their qualities; the same well often producing various grades.

Lead Poisoning

Lead poisoning results usually from breathing or swallowing lead in the form of its salts. In the smelting refining, and mining of lead it occurs more frequently than in other industries says R. R. Sayers in 'Miners Safety and Health Almanac', issued by the Bureau of Mines.

When lead occurs only as a sulphide (galena) the opportunity for lead poisoning is materially lessened, owing to the insolubility of the ore. When the ore is in the form of oxides, carbonates, or sulphates, it is much more soluble, and the danger of lead poisoning is proportionately increased. These lead salts are slightly soluble in water, and poisoning may result from drinking water containing them. Around smelters, in addition to the dangerous carbonate and oxide ores, the galena becomes changed, during the roasting and reducing processes, to these more soluble forms. The fumes from the sintering machines, blast-furnaces, etc., are dangerous, as is the dust about the charge-floors, feed-floors, flues, and bag houses.

The disease is usually chronic, but may have sudden increases in the severity of any or all of the symptoms simulating an acute attack. Constipation, headache, metallic taste, a blue line on the gums where they join the teeth, and abdominal cramps are common symptoms. In more severe attacks there may be marked anemia, wrist-drop, toe-drop, and convulsions.

The chief factors in the prevention of lead poisoning about mines and smelters are:

1. Mechanical means of handling lead-bearing material.
2. Adequate ventilation, usually artificial, for the control of dust and fumes.
3. Use of water freely to prevent the formation of dust.
4. Medical supervision, physical examination of workmen at regular intervals, and prophylactic treatments.
5. Education of the workman as to the causes of the disease and as to means of prevention.

In the education of the workman, instruction in personal hygiene plays an important part. He should never go to work without first having an ample meal (lead absorption is apparently more rapid when the stomach is empty); he should not work in his street clothing, but should have all of his work clothing washed frequently; he should not eat while working, nor smoke or chew tobacco; he should not put his hands about his face without having washed them first; he should drink water and milk plentifully, having first thoroughly rinsed his mouth; he should not allow himself to become constipated. When he has to work in fumes or dust, he should wear a respirator; when leaving work he should always take a shower bath; if he feels at all sick, he should consult a physician at once.

A flow of one second-foot of water equals 7.48 gal. per second or 40 miner's inches.

Mining in Alaska in 1920

•Mining in Alaska began in 1880 and up to the close of 1920 minerals had been produced to the value of \$160,240,000, over half of which is to be credited to the last decade. About 75% of this mineral wealth has come from the small but rich deposits termed bonanzas. Such deposits can be profitably exploited even under the most adverse conditions of isolation and transportation, because they yield large returns on the capital and labor employed.

Bonanza mining, always the first to be developed in a new land, is a most powerful agency in attracting population, in forming communities, and in establishing transportation systems. Such mining will continue, for the known bonanza deposits in Alaska have been by no means exhausted, and there is good prospect of finding others. A stable and permanent mining industry cannot, however, be founded on the exploitation of only the very rich orebodies. Permanency must be based on the development of the larger deposits of lesser unit value. Such development depends for its profits not so much on the richness of the ore as on economies made possible by the magnitude of the operations. Large mining operations cannot be successful at places that are served only by the haphazard and expensive means of transportation generally available on the frontier. The passage from bonanza mining to a stable and permanent industry has naturally taken place in all mineral-bearing regions and has long been under way in the accessible coastal region of Alaska, but the great mineral wealth of the Interior remains practically untouched except by the bonanza miner.

The minerals won from the large low-grade orebodies of Alaska have a total estimated value of \$105,000,000, most of it in gold, the remainder including the value of copper and other minerals.

The above estimate includes the output of (1) auriferous lodes, whose gold and silver content is valued at less than \$2.50 per ton, (2) copper ores containing an average of not more than 3% of copper, (3) placers having a gold content worth less than 75c. per cubic yard, and (4) marble and gypsum of south-eastern Alaska. The output of

the low-grade deposits has come mainly from the gold mines of Juneau, but it also includes the product of some of the larger copper mines of Ketchikan and Prince William sound and a large part of the gold recovered by dredging in Seward Peninsula. All the low-grade deposits thus far developed are at or near tidewater and have therefore not had to bear the high cost of land transportation, which can be borne only by bonanza deposits. Many mineral deposits of low grade are known in Alaska, and the prospect of finding others is good.

The long interdict on the use of the mineral fuels of Alaska has greatly retarded all forms of mining in the

MAP OF ALASKA

Territory. It not only enhanced the cost of all mining by prohibiting the use of local fuels, but it made the industry lose the advantage of the improvement in industrial conditions that would certainly have followed the development of coal and oil.

The situation was relieved somewhat by the coal-land leasing act of 1913, but unfortunately this relief came at about the time when unstable industrial conditions were brought about by the War and by the readjustments that followed peace. In 1920 further help was given by the passage of an oil-land leasing act, but it has been passed too recently to affect the Alaska mining industry as yet.

As about 96% of the value of the mineral output of Alaska has been taken from her gold and copper mines, the world-wide depression in the mining of these two metals, which continued through 1920, has been a staggering blow to the prosperity of the Territory. About

60% of the population of Alaska has heretofore been directly or indirectly supported by gold mining. With the relative decrease in the value of gold the miner and prospector have been forced to leave the Territory and the population has declined. This decline, however, must not be regarded as an indication of the early exhaustion of the gold resources, for Alaska contains enormous potential reserves of gold and other minerals.

Though the mining industry of Alaska as a whole suffered a serious depression in 1920, yet the value of the total mineral output was greater than in 1919, chiefly because of the great increase in the production of copper, largely to be credited to the four large copper mines controlled by the Kennecott Copper Corporation. The value of the total mineral production of Alaska was \$19,620,913 in 1919 and about \$22,070,000 in 1920. The output of the gold placers has decreased, but that of the gold lode mines has been maintained.

Value of Mineral Production in Alaska in 1919 and 1920

	1919	1920
Gold	\$ 9,426,032	\$8,000,000
Copper	8,783,063	12,400,000
Silver	705,273	900,000
Platinum and allied metals.....	73,663	80,000
Tin	73,400	20,000
Lead	72,822	142,000
Coal	343,547	380,000
Petroleum, marble, gypsum, quicksilver, etc.	143,113	148,000
Total	\$19,620,913	\$22,070,000

One of the most encouraging features of the year's mining was the systematic development of a large auriferous lode in the Nixon Fork (McGrath) district in the upper Kuskokwim valley. This orebody gives promise of being valuable, and if it so proves it will assure the beginning of a lode-mining industry in this remote region. Auriferous mineralization appears to be rather widely distributed in the Kuskokwim basin, a region which has been relatively little prospected.

The discovery of this lode and the continued success of the Candle Creek dredge, near McGrath, has attracted attention to the Kuskokwim basin, and there has consequently been more prospecting in this Province than in any other part of inland Alaska. Especially noteworthy has been the considerable search and tests for dredging ground in the Kuskokwim and immediately adjacent region during the last two years.

Though lode mining in south-eastern Alaska is still chiefly confined to the low-grade ores of Juneau, whose development is most seriously handicapped by existing conditions, yet there was in 1920 a marked increase in the prospecting for auriferous lodes in this field, notably in the Sitka district. Some promising discoveries of auriferous quartz were made on Chichagof island.

Important also are the activities in the Willow Creek district, tributary to the Government railroad, directed to the consolidation of some auriferous lode properties and their development on a large scale.

One of the most important events of the year was the beginning of systematic underground exploration of the Matanuska coalfield under the auspices of the Navy Department. This exploration has for its purpose the de-

velopment of high-grade coal for the use of the Navy, but incidentally it will afford a thorough test of the commercial possibilities of the field.

The enactment of the oil-leasing law in February 1920, together with the world-wide search for petroleum, has again attracted public attention to the oil in Alaska. There has not yet been sufficient time to drill under the new regime, but more than half a million acres of land has been staked on the assumption that it is oil-bearing. The evidence at hand indicates that though a part of this land is well worth drilling many locations, as during all oil booms, will be found worthless. There is, however, good prospect of developing producing wells in Alaska.

During 41 years Alaska has produced gold to the value of \$320,000,000, of which \$221,642,000 is to be credited to her placer mines. For reasons already stated there was less placer mining in 1920 than in 1919, and the outlook under present economic conditions for a revival of the industry as a whole is not hopeful. In the following table the production of placer gold in Alaska in 1919 and 1920 is allocated by regions. This table shows clearly that the decrease in output is due chiefly to the decline in the production of the more isolated districts.

Estimated Value of Placer Gold Mined in Alaska in 1919 and 1920

Region	1919	1920
South-eastern Alaska and Pacific Coast region....	\$30,000	\$10,000
Copper River Basin	185,000	175,000
Cook Inlet and Susitna region.....	110,000	65,000
Yukon Basin	2,910,000	1,725,000
Kuskokwim Basin	350,000	400,000
Seward Peninsula	1,360,000	1,240,000
Kobuk region	25,000	15,000
	\$4,970,000	\$3,630,000

In 1920 there were 17 gold dredges operated in the Seward Peninsula, 2 in the Iditarod and Fairbanks districts, and 1 in the Mount McKinley (McGrath) district. Improvements are being made in the Cache Creek dredge in the Yentna district, and this will probably be operated next year. Plans are also being made for installing two dredges in the Innoko district, and for the exploitation of other dredging ground in the Kuskokwim region. Owing to the present high operating costs most dredging companies will consider only placers whose gold content is 75c. or more per cubic yard. The average recovery of the dredges in Seward Peninsula in 1919 was only 52c. per yard, and the extensive reserves of dredging ground in the Peninsula are consequently now attracting little attention.

It is estimated that 15 gold lode mines and five prospects were operated in Alaska in 1920, producing about 3,270,000 tons of ore, from which \$4,360,000 worth of gold and 106,000 oz. of silver were recovered. The output in 1919 was 3,262,573 tons of ore, containing gold to the value of \$4,392,237 and 108,691 oz. of silver. Seven of the gold mines operated in 1920 were in south-eastern Alaska, five in the Willow Creek district, two at Fairbanks, and one in the Copper River region. The prospects, which made only a very small output, are in Kena and Seward peninsulas and in the Fairbanks district.

Eight copper mines were in operation in 1920 produc-

MAP SHOWING MINES NEAR TREADWELL AND JUNEAU, ALASKA

ing 330,000 tons of ore from which 71,000,000 lb. of copper, 710,000 oz. silver, and \$12,000 worth of gold were recovered. This brings the total copper production of Alaska to 616,000,000 lb. of which more than half is the output of the last decade.

As in past years only four mines made a large output; one of these is on Prince William sound and the others are in the Kotsina-Chitina district.

The Rush & Brown was the only copper mine operated in the Ketchikan district during 1920, though some copper was recovered from the platinum and palladium ores of the Salt Chuck mine. Developments were continued in copper-gold property on William Henry bay, in the Skagway district. On Prince William sound the output of the Beatson-Bonanza overshadowed all other operations. At the adjacent Girdwood mine much work was done and preparations were made to install a mill. Systematic development of the Rhea Cove copper property was continued during a part of the summer. The Schlosser mine, on Fidalgo bay, was operated on about the same scale as in the past, and some copper was produced in the course of work at the adjacent McIntosh mine. Except for some prospecting and assessment work there were no other copper developments on Prince William sound. In the Kotsina-Chitina district some work was done on a number of copper properties, but the only productive mining was that at the Kennecott group of mines. Some new deposits of copper ore were discovered in 1920 in the region tributary to the Government railroad, but there were no important developments.

In 1920 Alaskan mines produced about 887,000 oz. of silver; in 1919, 488,034 oz. The lead production increased from 564 tons in 1919 to about 880 tons in 1920. The increased output of silver was largely won from the copper ores, but this increase like the increase in the production of lead, was in part won from galena ores mined in a small way at several localities. The largest ship-

ment of galena ore was made by a small mine in the Kantishna district.

About 31 tons of stream-tin concentrate was mined in Alaska in 1920, compared with 86 tons in 1919. Most of this tin was mined in the York district, at the west end of Seward Peninsula, where one dredge and several small operators were working on placer tin deposits. Several tons of stream tin was also recovered from gold-placer mining operations in the Hot Springs and Ruby districts, but this was not shipped. A total of 35 tons of stream tin was shipped from Alaska in 1920, but a considerable part of this was mined in previous years.

The gold placers of the south-eastern part of Seward Peninsula, from the Chistochina (Slate Creek) district, and from some other districts, continued to yield some platinum in 1920. The Salt Chuck lode mine, in the Ketchikan district, also continued to produce platinum and palladium, as well as copper, in 1920.

Work was continued at the Parks quicksilver mine, on lower Kuskokwim river, in 1920, and some cinnabar ore was produced. A small shipment of cinnabar ore was also made from a prospect in the same district.

At the Mt. Morgan mine in Queensland, Australia, two compound May jigs have been added to the concentrating plant to take $\frac{1}{8}$ -in. ore from rolls, and the tailing from the Hancock jigs after it has been fine-ground through rolls. The tailing from the new jigs goes to a three-compartment spitzkasten, the underflow from which goes to tube-mills, and the overflow to Wilfley tables. The May jig concentrate goes to a trommel, which separates it into under and over $\frac{3}{32}$ in., the oversize going direct to the smelters with the Hancock-jig concentrate, and the undersize to the sinter plant, after a small proportion is separated by a classifier and added to the product sent to smelters. A 35-ft. Dorr thickener has also been added to the plant.

Karl Eilers v. Guggenheims

Herewith we give the text of the letter addressed by Mr. Eilers to his fellow-stockholders.

January 6, 1921.

To the Stockholders of the

American Smelting & Refining Company.

Gentlemen:

Doubtless you have seen in the public press of recent issues the many articles concerning the Messrs. Guggenheim and their unfortunate administration of the affairs of the American Smelting & Refining Company. From these articles you may have gained the impression that the outlook for the company is not promising and may have considered the advisability of selling your stock. In view of this possibility, I feel impelled to advise against any such sale. I most strongly urge you to retain your stock. In my judgment with proper management the future for our company is bright. The opportunities for development I believe to be practically limitless, provided the strangle-hold of the Messrs. Guggenheim on our company is broken.

To that end I have decided to urge upon the stockholders the election at the next annual stockholders' meeting of a Board of Directors whose only interests will be those of the company and its stockholders, in order to place the American Smelting & Refining Company in the predominant place which it should occupy in the basic industry of mining, smelting and metal refining.

To show the necessity for such action I consider it my duty to make known certain facts.

When the Guggenheim family first came into the company their interest was a thirty-five million dollar one. It now appears that they have disposed of about 90% of their stock.

While in control of the company's affairs the Messrs. Guggenheim have secured and developed many other enormous mining properties, not for the company's account, as should have been the case, but for their personal benefit, in marked contrast with the way that other similar industrial organizations have been built up.

With an ownership so small and with their personal interests elsewhere it could hardly be expected that the Guggenheims would look upon the A. S. & R. Co. as their first consideration.

As indicative of this, very recently it has been announced that the Selling Agency for the copper production of the

Utah Copper Company,
Nevada Consolidated Copper Company,
Chino Copper Company,
Chile Copper Company,
Braden Copper Company,
Ray Consolidated Copper Company,
Beatson Copper Company,
Kennecott Copper Company,

was transferred from the American Smelting & Refining Company to Guggenheim Brothers, Inc. This deprives the American Smelting & Refining Company of commis-

sions aggregating from \$750,000 to \$1,000,000 per year.

You should also know that there have been losses of millions of dollars caused by the Guggenheims changing the policy of marketing copper, and adopting one which seems nothing less than gambling, such as selling copper for future delivery without at the same time protecting the company, and also withholding copper from sale when it ought to have been sold and until a serious drop in price had occurred. Instead of a large cash balance and several millions in Liberty bonds, the situation a year ago, the bonds have been sold and the company has been obliged to borrow several millions of dollars.

The power of the Guggenheims in the affairs of the company has depended on the acquiescence of the stockholders who, not knowing that they had quietly sold out most of their holdings, have continued year after year sending proxies as requested, and thus perpetuated the control of the Guggenheim board.

In the light of recent disclosures, do you desire to continue this policy? If not, the remedy is to take the management of the company into your own hands, and, at the forthcoming annual meeting in April, eliminate the Guggenheim influence from the Board.

To that end, I seek your co-operation and constructive help. If you wish me to represent you, the enclosed form of proxy to Mr. Edward D. Emerson, of Boston, another stockholder of long standing, and myself, should be signed and returned to the above address. In any event, I invite you to communicate and consult with me.

Unless you are satisfied with the showing which the company has made in the past, I urge that without the fullest investigations you do not comply with official or other requests for proxies which may be used in the interests of the Guggenheims.

There have been many other acts to the serious detriment of the company, but at this time I will not enlarge upon the reasons why your interests demand a change of management. Some of them are set forth in the enclosed copy of the article which appeared in the New York 'Tribune' of December 21, which I ask you to read.

Very truly yours,

KARL EILERS.

THE production of primary metallic zinc from domestic ores in 1920 was about 449,000 tons and from foreign ores about 14,000 tons, a total of 463,000 tons, compared with 452,272, 13,471, and 465,743 tons, respectively, in 1919. Of the output of domestic zinc in 1920 about 51,000 tons consisted of electrolytic zinc, as compared with 27,056 tons in 1919. In addition to primary zinc there was an output of about 20,000 tons of re-distilled secondary zinc, compared with 19,748 tons in 1919, making a total supply of distilled zinc and electrolytic zinc in 1920 of 483,000 tons, of which 81,000 tons was high-grade zinc, 34,000 tons intermediate, 51,000 tons select and brass-special, and 317,000 tons of prime Western. The production of the corresponding grades in 1919 was 45,377, 39,173, 140,917, and 260,024 tons, respectively, a total of 485,491 tons.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

CATTLEMEN CLAIM DAMAGE TO RANGES FROM SMELTER SMOKE.

JEROME.—Cattlemen of the Verde valley are claiming large damage to range grass through the action of sulphuric gases settling from the stacks of the United Verde smelter at Clarkdale and the United Verde Extension smelter at Clemenceau. Before the reduction works were built there were many farms in the vicinity, and as the owners established claims for damages in the courts their holdings have been purchased by the companies, which have acquired large acreage in what are called 'smoke farms'. The claim that range grass is injured in a like manner is something new.

MIAMI.—Assessment work amounting to \$6000 has been completed by the Miami Consolidated Mines Co. on 60 unpatented claims by the sinking of shafts and tunneling. Notices have been posted on all claims showing that the assessment work has been completed.

TUCSON.—A good showing of chalcopryite is reported to have been opened in the new shaft of the Arizona-Tucson Mining Co. in cutting a station on the 650-ft. level. The ore was entered in driving north toward the big ore-shoot that shows on the surface, and is taken as an indication that the orebody in the glory-hole goes to that depth and changes to sulphide. Operations on the Saginaw property, adjoining, will be undertaken shortly, and the shaft sunk to a depth of at least 1000 feet.

BISBEE.—The Junction mine, the principal property of the Calumet & Arizona Mining Co., was closed down for five days last week while a new air-line was being installed in the shaft. It was found necessary to increase the size of the old line.

HAYDEN.—It is announced that a company represented by Hugh H. Hanger, of Washington, D. C., has purchased the '79' mine from the Continental Commission Co. The terms of the purchase have not been revealed, but it is understood that a large cash payment is to be made, part of which has just been paid to close the deal. The property was owned by Dennis O'Brien, who held it since 1879 and who refused to sell. At O'Brien's death the property passed to his brother, then in turn to his heirs, from whom it was purchased about a year ago by the Continental Commission Co. The property consists of 23 mining claims and prior to a year ago had not been prospected to any great extent. The ore is lead-silver and copper. During the past year 70 cars of high-grade ore were shipped to El Paso.

MEYER.—It is announced by the management of the Binghamton mine that development will be resumed in 90 days to make preparations for full-scale production when the copper market is again normal. It is intended to put on about 40 men.

OATMAN.—Development work has been resumed at the Gold Road mine. A cross-cut is being run to cut the vein on the 650-ft. level; 60 ft. of work has yet to be done. Ore on the 200-ft. level has been opened that is said to run \$100 per ton for a width of three feet.

COLORADO

MINING BY LESSEES AT CRIPPLE CREEK IS ACTIVE

ASPEN.—Mining and transportation rights having been secured by John T. Boyd, mining engineer, operations will shortly be resumed on properties intersected by the Cowenhaven tunnel. Among the properties to be developed are the Homestead or Koch ranch property on Hunter creek, three miles north of Aspen. The tunnel traverses many of the older producers of high-grade ore. A force of men is at work clearing out the tunnel and laying track, and other men are employed overhauling machinery in the Hunter Creek mill and getting the mill in shape to resume treatment.

CRIPPLE CREEK.—A depth has been attained of close to 850 ft. with the diamond-drill prospecting in the north-eastern section on Galena hill. Production for January is expected to show material increase, as practically all mines operating are working full-handed and daily shipments are above the December average. Work at many properties has been resumed under lease.

Gold ore, bringing settlement at the Golden Cycle mill at the rate of \$120 per ton, is being mined on the Rankin lease on the Jerry Johnson mine on Ironclad hill. The property adjoins the Hardwood of the United Gold Mines Co., whose lessees continue to ship high-grade ore.

DENVER.—The Colorado Chapter of the American Institute of Mining and Metallurgical Engineers at the recent annual meeting elected Richard A. Parker chairman for the ensuing year; F. G. Gilbert, vice-chairman; H. F. Lunt, secretary-treasurer; and R. M. Henderson, member of the executive committee.

GEORGETOWN.—Miners are engaged cleaning out the Burleigh tunnel, preparatory to resumption of work on the Dives Pelican mine. G. L. Cole and Missouri associates plan to extend the Capitol drift into Colorado Central ground. The heading of the Capitol lateral is about 1000 ft. distant from the known orebody exposed

in the workings of the Colorado Central shaft and will cut the vein 400 ft. deeper than the present workings. The mill is also being overhauled preparatory to treatment of low-grade ores left in the Dives-Pelican stopes. The Bellevue-Hudson is active under lease and ore is being saved for shipment.

IDAHO SPRINGS.—The Humboldt property on Ute creek, idle since operated by the late Julius Heil, who mined and shipped a good tonnage of high-grade ore from the mine, is again active under lease to the firm of Egan & Rufenacht of this city. The lessees are operating in one of three adit-tunnels on the property, all of which have produced ore in the past.

MICHIGAN

COPPER PRODUCTION.—J. PARKE CHANNING IS OPTIMISTIC.

CALUMET.—December production of the Calumet & Hecla group, totaling 7,514,300 lb., is an increase of 678,517 lb. for the same mines over November. Ahmeek's refined copper output of 1,914,500 lb. compares with 1,840,000 for November; Calumet & Hecla's production of 4,754,000 compares with 4,227,099 for November; and Isle Royale's output of 845,800 compares with 768,684. The total reported by Calumet & Hecla and subsidiaries is actually 7,517,712 lb., the difference between this total and the one given above being represented by a small clean-up of copper from subsidiaries now closed. The total December production represents an increase of 190,949 lb. over the November total of 7,326,763. The November figures included 436,286 lb. produced by Osceola, representing about a half month's output, the Osceola closing on November 16, also copper produced during the half month by LaSalle and White Pine. The increase in December reflects a gain in efficiency in the underground departments; another important factor was the successful employment of automatic level scrapers in the Calumet & Hecla. The increase from Calumet & Hecla alone is particularly notable, inasmuch as the November figures included a half month's operations from the Osceola lode shafts, while the December output came entirely from conglomerate openings.

That J. Parke Channing, president of Seneca, now here on a visit of inspection, is a firm believer in the permanency of the Lake Superior copper districts was evidenced by a remark he made in an interview to the effect that "the mines of Michigan will be running when the porphyries are all closed up". He declared this district to have a great future, due to the uniformity and extent of its copper-bearing lodes and the vast area they traverse, the greater part of it as yet untouched. He believes recovery in the metal market will be much earlier than expected by many people and that Europe soon will be in the market for large quantities. Mr. Channing expressed himself as well satisfied with developments both in the Seneca and Gratiot properties. On his return East he will arrange for permanent hoisting equipment. It was the original intention to sink the Seneca shaft to the 8th level, but it now will be extended to the 10th. The

shaft has just reached the 6th and a drift on that level is to be started. Gratiot, now bottomed at the 13th, having been in the lode almost from the grass roots, will be sunk to the 33rd, a distance of about 2000 ft., at which point it will be connected with the Seneca shaft. It is believed this work can be done in a year's time.

The leaching plant of the Calumet & Hecla is still producing about 1,000,000 lb. of copper per month, of which 600,000 lb. is from the reclamation plant. Work on the Tamarack reclamation-plant buildings will be started in the spring. Early delivery of steel is expected. Much of the material, however, will be that salvaged from the old Calumet coal storage. Construction work will require the rest of the year to complete. The building for the re-grinding unit already is erected and machinery will be installed during the summer.

NEVADA

THE PEAVINE MOUNTAIN DISTRICT.

RENO.—The Peavine Mountain district, including the territory surrounding the mountain of that name north of Reno, has been attracting attention since the organization in December of the Peavine Mine Operators' Association, which has been active in bringing the district before Nevada mining men with the result that a number of additional companies have started or are planning to start work. Now development work is being done by the Black Panther, Standard Metals, Fravel Paymaster, Hager and Keefer, the Nevada Western, and the newly organized Reno Silver & Copper Co., with three other companies getting ready to start in the spring. The principal content of most of the ore of the district is silver, with a high gold and a low copper content. The vein in the Standard Metals strikes north and dips west at 35 to 50°, being more nearly vertical on the 300-ft. or bottom level, which is now being explored with a drift on the foot-wall of the vein and cross-cuts. The ore at this depth is 10 to 30 ft. wide and the average value of 5 to 10 ft. on the foot-wall is \$20 to \$30, with a narrow seam that assays much higher. This ore-shoot has been opened on the 100 and 200-ft. levels for a length of 125 ft. and an extreme width of 50 ft. The water-level is at 200 ft. The drift on the 300-ft. level is being continued and it is planned to raise to the 100-ft. level and sink the shaft another 100 ft. The ore contains neither lead nor zinc and in the summer of 1919 the company completed a 60-ton concentrator and flotation plant in which the combined processes gave one ton of concentrate and floated material to 11 tons of ore. A crusher, rolls, and a ball-mill are used, the last reducing the ore to pass 60-mesh before it is concentrated on Wilfley tables, which recover 50 to 60% of the metal. The tailing from the tables is re-ground to pass 100-mesh and this is treated in a K & K flotation machine. The Fravel Paymaster adjoins the Standard Metals on the strike of the vein and the shaft is being sunk 300 ft. from the 200-ft. level, where the orebody is 300 ft. long and 5 ft. wide, with a maximum width of 10 ft. The company plans to have ore treated in

the Standard Metals plant when it re-opens in the spring. The companies operating in the district are spending \$25,000 monthly and it is estimated that this will be increased to \$50,000 by the greater activity that is promised for the next few months.

KLONDYKE.—Two 50-ton carloads of \$35 silver-gold ore are being shipped weekly from the Golden State, where an orebody nine feet wide is being mined at a depth of 60 ft. A winze is being sunk from the 60-ft. level. The ore is at a well-defined contact between limestone and rhyolite. The Golden State is being worked under a bond and lease by the Knox Divide. Regular shipments of \$11

is stated that the average cost of producing lead in this State during 1920 was 6.06c. per pound, whereas the current price is 4.75c. Imer Pett, general manager for the Bingham Mines Co., has returned from Washington and expresses the opinion that the next Congress will place a higher tariff on lead imports.

During the week ending January 15, the Utah Ore Sampling Co. released 98 cars of ore from Utah mines and four from Nevada mines at its Murray sampler; at the Tintic plant, 34 cars of Utah ore were handled.

EUREKA.—Connection has been made between the No. 1 shaft at the Tintic Standard property and the new

THE UTAH-APEX MINE AT BINGHAM, UTAH

to \$17 ore are being made from the Maloney lease on the Original Klondyke, the material coming from dumps. Two sub-lessees are working and one of these, the Collier-Jones-Erickson, has ready a 50-ton shipment that is expected to net \$30 per ton.

UTAH

MINING OPERATORS ARE SEEKING INCREASED TARIFFS ON LEAD.

SALT LAKE CITY.—A memorial to the national Congress, calling attention to the necessity for an increased duty on lead, was presented to the State Senate on January 20. The measure has the backing of the Utah Chapter of the American Mining Congress. The memorial calls attention to the fact that the market price of lead has receded to the level that existed before the world war, while the high cost of production is unchanged. It

works, at a depth of 1200 ft., this being the second connection, the first being on the 1000-ft. level. The second connection has resulted in better ventilation and also enables better access to some large stopes of ore. It is expected that the company's new milling plant will be in operation by February 1. During the week ending January 14, the company shipped 77 carloads of ore, which establishes a new high record for output from any one mine in this district.

During the week ending January 14, the mines in this district shipped 184 carloads of ore, of which the Tintic Standard leads with 77; Chief Consolidated, 31; Dragon, 16; Iron King, 15; Eagle & Blue Bell, 15; Victoria, 8; Iron Blossom, 7; Bullion Beck, 3; Grand Central, 3; Swansea, 3; Colorado, 2; Eureka Mines, Sunbeam, Eureka Hill, and Centennial, 1 each.

On the 1565-ft. level of the Iron King mine, two head-

ings are being driven, according to N. W. Roberts, superintendent. One of these drifts recently entered an important break, fully six feet wide, and which is now being followed to the north-east. The second drift on that level is being driven to the south-west. Most of the shipments coming from the property at present are obtained above the tunnel-level, which is under lease to one of the smelting companies. It is expected that the output of iron ore will shortly be increased to 100 tons per day.

PARK CITY.—Ore shipments from this district for the week ending January 15 totaled 1911 tons, of which the Judge Allied Companies shipped 600; Silver King Coalition, 505; and the Ontario, 600.

BRITISH COLUMBIA

ORE-SHIPMENTS ARE MADE FROM PORTLAND CANAL DISTRICT.

STEWART.—Shipping from the Premier mine to Stewart is now well under way. In its last trip south the 'Prince Albert' took a consignment of 400 tons, and another 500 tons will go forward on the next trip. The first consignment of 450 tons is said to have given a return of \$400 per ton. The Algonquin Development Co. is making preparations for the shipping of some 100 tons of ore that have been taken out in development, and horses have been taken into the property for the purpose. These have been provided with snowshoes. The ore is complex, containing sulphides of zinc, lead, copper, and iron, and some of it assays thousands of ounces per ton in silver.

CLINTON.—Considerable local excitement has been caused by the finding of gold in the direction of Scottie creek, on the Cariboo road, and more than 100 claims have been staked. Some of the assays that have been made are said to run high in gold. In some of the discoveries the gold occurs associated with limonite.

ATLIN.—The placers of the Atlin district have not been bringing the returns nor furnishing the employment that they did in past years and residents are looking forward to the development of lode-mining properties. The property upon which they chiefly depend is the Engineer. When its title is established by the courts it is asserted that the Guggenheims will take over this mine and operate it. Atlin people, therefore, want to see the litigation brought to an issue without delay. The purchase of the Engineer by a concern having adequate financial resources would mean not only the exploitation of that property but the acquirement and development of a considerable adjacent area.

ALICE ARM.—It is said that the Bellevue group, in the Illiance River district, is showing up well, there having been uncovered a well-defined vein, samples from which have assayed 23.05 oz. of silver per ton, 0.07 oz. gold, and 3.4 to 5.4% lead. Work is proceeding this winter and the syndicate in control proposes installing a concentrator next season. The operating company is known as the Alice Arm Consolidated Holdings, Ltd.

VANCOUVER.—The Annual Convention of the western division of the Canadian Institute of Mining and Metallurgy is to be held at Vancouver on February 9 to 11. A

first-class program has been prepared, among the speakers being S. J. Schofield, of the geological department of the University of British Columbia. Another contributor will be J. D. MacKenzie, of the Canadian Geological Survey.

ONTARIO

LAKE SHORE DEVELOPS ITS NEW ORE-SHOOT.

KIRKLAND LAKE.—An ore-shoot, stated to be richer than any other gold deposit so far developed in Northern Ontario and ranking in importance with the big ore-bodies of Porcupine, has been developed at the Lake Shore. No. 2 vein has been opened up for 2000 ft. on the 200-ft. level and for over 1000 ft. on the 400-ft. level. Over 1500 ft. on the upper level is in high-grade ore, one stretch of 600 ft. being solid ore from 5 to 40 ft. in width. The richness of the ore is indicated by the fact that the recovery, principally from development ore from this vein, has averaged \$25 per ton. In 1917 the then manager of the mine estimated that No. 2 vein contained indicated ore of the value of \$800,000. At that time it had only been opened up 400 or 500 ft. on one level. Since then the known orebody has been at least quadrupled by underground work. No. 1 vein, which in 1917 was estimated to contain ore to the value of \$400,000, has undergone development on the 400-ft. level which has largely increased the ore-reserves.

COBALT.—No further curtailment of operations on account of power-supply is anticipated, as it is not believed that conditions will become any worse until the spring floods bring relief. The substantial decline in operating costs due to the wage reduction of 75c. per day, announced for February 15, encourages the hope that even at present prices of silver the scope of operations at producing mines will be largely increased and work resumed on many properties now idle.

An important discovery has been made on the first level of the University property of the La Rose Consolidated, where a new vein, two to four inches wide, of high-grade ore has been found. The high-grade averages 1500 oz. per ton, with three feet of good milling rock.

The new vein opened up on the 250-ft. level of the Bailey continues strong under development and in some sections contains ore assaying from 1000 to 4000 oz. per ton.

The Crown Reserve has discontinued diamond-drilling, having reached a depth of 1500 ft. without making any discoveries of importance. No work is being done except keeping the mine free of water.

BOSTON CREEK.—At the Allied Gold Mines adjoining the Miller Independence on the north several thousand feet of diamond-drilling has been done with fair results, the drill having cut what is thought to be an extension of the 'D' vein, with indications of good gold content.

GOWGANDA.—In sinking the shaft on the 'office' vein of the Castle property from the 80-ft. level to a depth of 150 ft. a new vein carrying two inches of high-grade ore and a good width of milling rock was found. Seventeen tons of high-grade ore has been shipped.

THE MINING SUMMARY

CONFERENCE OF BUREAU OF MINES OFFICIALS AT BERKELEY

The following engineers for the U. S. Bureau of Mines are attending the conference of Bureau officials held at the Pacific Experiment Station, Berkeley, during the week beginning January 24:

D. A. Lyon, Chief Metallurgist and Supervisor of Stations, Washington, D. C.; E. A. Holbrook, Executive Officer in charge of the Investigations Branch and Chief Metal Mining Engineer, Washington, D. C.; D. Harrington, Supervising Mining Engineer, Denver; H. E. Meyer, Chief Clerk, Washington, D. C.; O. C. Ralston, Superintendent Northwest Experiment Station, Seattle; S. C. Lind, Superintendent Rare and Precious Metals Experiment Station, Reno, Nevada; Thomas Varley, Superintendent Inter-Mountain Experiment Station, Salt Lake City, Utah; C. E. van Barneveld, Superintendent Southwest Experiment Station, Tucson, Arizona; L. H. Duschak, Superintendent Pacific Experiment Station, Berkeley; B. O. Pickard, District Mining Engineer, Berkeley; C. P. Bowie, Petroleum Engineer, San Francisco; E. D. Gardner, Mining Engineer, Reno; W. C. Riddell, Chemical Engineer, Berkeley.

In addition there are present the deans of the schools at which the various experiment stations of the Bureau are situated. They are:

Dean Milnor Roberts, School of Mines, University of Washington, Seattle; Dean F. C. Lincoln, School of Mines, University of Nevada, Reno; Dean Joseph F. Merrill, School of Mines, University of Utah, Salt Lake City, Utah; Dean G. M. Butler, College of Mines and Engineering, University of Arizona, Tucson; Dean F. H. Probert, College of Mines and Metallurgy, University of California, Berkeley.

Reports were received in regard to the research work in progress at the various Experiment Stations and the plans for the future work were discussed. The subjects considered at this conference include the co-ordination of the work of the Bureau of Mines in the West and the plans for closer co-operation between the Bureau and the several universities at which Experiment Stations have been established. Co-operation between State organizations and mining companies was also discussed.

PRODUCTION OF GOLD AND SILVER

The Bureau of the Mint, with the co-operation of the U. S. Geological Survey, has issued the following statement of the preliminary compilation of the production of gold and silver in the United States during the calendar year 1920:

State	Gold, oz.	Value	Silver, oz.	Value
Alaska	380,034	\$7,856,000	792,751	\$804,745
Arizona	239,118	4,943,000	6,098,251	6,190,518
California	692,019	14,305,300	1,513,495	1,536,394
Colorado	368,298	7,613,400	5,572,407	5,656,718
Idaho	22,509	465,300	7,531,253	7,645,201
Michigan			510,601	518,326
Missouri	19	400	123,219	125,083
Montana	88,971	1,839,200	13,583,164	13,788,877
Nevada	171,968	3,554,900	7,392,689	7,504,540
New Mexico	22,417	463,400	764,586	776,154
Oregon	46,687	965,100	182,558	185,320
South Dakota	203,243	4,201,400	84,351	85,627
Tennessee	280	5,800	112,595	114,299
Texas	5	100	524,212	532,143
Utah	100,446	2,076,400	11,564,155	11,739,121
Washington	7,198	148,800	183,437	186,213
Philippines	51,568	1,066,000	21,917	22,249

TARIFF ON ZINC

Zinc producers as well as smelters are said to favor an increased duty on zinc ore. Obviously if the duty on ore is raised then the duty on slab and sheet zinc should also be raised for otherwise the smelters and rollers would be placed in an embarrassing position. Reports are to the effect that the committee of the American Zinc Institute, which presented argument for a tariff to the Ways and Means Committee asked for a tariff of from two to four cents per pound. Other advices are that the committee asked for the restoration of the duties that applied under the Aldrich-Payne Act in 1909. The following comparison of the tariffs of 1909 and 1913, the latter being that which now is in effect, is made:

	1909 cents	1913 %
Zinc ore containing		
Less than 10 % zinc.....	free	10
10 to 20 % zinc.....	1*	10
20 to 25 % zinc.....	1*	10
Over 25 % zinc.....	1*	10
Slab zinc (spelter)	1½	15
Zinc sheets	1½	15
Zinc oxide (dry)	1	10

*On the zinc contents.

On the present value of zinc in Europe the duty of 15% ad valorem is equal to around 70c. per 100 lb. or about one-half the duty which applied under the tariff of 1909.

SILVER EXPORTS FROM MEXICO

The new rates of export duty on silver, according to the decree just issued by President Obregon, are given below. When the value of silver on the New York market, as determined by the Secretary of Hacienda, either in ten-day or monthly periods, is less than 60 cents per ounce, no duty will be levied.

Value of silver	Duty to be levied, % ad valorem
\$0.60 to 0.70	1
0.70 " 0.80	1½
0.80 " 0.90	2
0.90 " 1.00	7
1.00 " 1.10	8
1.10 " 1.20	9
1.20 " 1.30	10
1.30 " 1.40	11
Greater than \$1.40	12

The decree of June 15, 1920, is abrogated under the terms of the new decree. The purpose, as stated, is "to co-operate for the solution of the present prices in the mining business and to protect the mining companies sufficiently to enable them to make profit and at the same time contribute to the Government in proportion to their earnings".

CANADIAN GOVERNMENT URGED TO PURCHASE SILVER AT EIGHTY CENTS

The latest organization to urge relief for the silver-mining industry in British Columbia by Government action is the Board of Trade of Nelson, B. C. The resolution follows in part:

Whereas the present unemployment amounts in effect to

an industrial crisis and it is desirable and behooves every good and loyal citizen to avert such crisis, and

Whereas, owing to the high cost of production, many mines have been forced to suspend operations, since it is unprofitable to mine for silver at the present variable prices of the metal, and,

Whereas there is of necessity much unemployment and suffering throughout the country, and,

Whereas the establishment of the silver industry would ameliorate this state of affairs, now, therefore, be it hereby,

Resolved that this Board of Trade urges the Dominion government to take such legislative action as may be necessary to secure: (a) The control and purchase of all silver produced in the Dominion at a fixed price of eighty cents per fine ounce for a period of two years or so much shorter or longer a time as may be necessary to secure the desired objects; and (b) The withdrawal of an agreed amount of one dollar bills from circulation and the substitution of minted silver dollars:

Be it further resolved to draw the attention of the Dominion government to the fact that the United States continues to purchase silver under the Pittman Act at 99½c. per ounce and to issue silver currency in lieu of paper money, and that still further coinage is advocated, thereby removing the metal from the world's market and making for the maintenance of silver values at a price higher than the 80c. per ounce mentioned at the opening of this resolution.

ARIZONA

Ajo.—J. C. Greenway, general manager for the Calumet & Arizona and New Cornelia mining companies, Cornelius Kelly, president of the Inspiration Copper Co., Will Thornton, of the Greene-Canea Copper Co., Thomas Cole, of the Calumet & Arizona Mining Co., and L. D. Ricketts, consulting engineer for the Phelps Dodge interests and other mining corporations in the South-West, are here for the purpose of considering the proposed railroad to the Gulf of California, with a terminus at Rocky Point. A preliminary survey for the line has been completed.—The average cost of producing copper by the New Cornelia company during 1920 was less than 13½ cents per pound, despite a curtailed scale of operations. The output was 40,761,446 lb. as compared with 39,000,000 lb. in 1919.

CALIFORNIA

Angels Camp.—The new mill and cyanide plant at the Sheep Ranch mine are now operating, 100 tons of medium-grade ore being crushed daily and 90 men being employed in the mine and mill.—The improvements recently made in the mill of the Calaveras Consolidated company are proving to be of great advantage. New ore is being opened in the lower levels of the mine.

Chico.—J. M. Pitts, of San Francisco, has resumed operations at the Bader mine. A contract has been let for driving a 400-ft. tunnel to develop the ground south of the old workings, which yielded large amounts of rich ore years ago.—A new 'lead' of rich gravel is reported in the Butte mine, and additional equipment will be installed to assist operations.

Jackson.—The 3500-ft. point has been passed in unwatering the Argonaut and Kennedy mines. A wide vein of good ore on the 4900-ft. level of the Argonaut is the principal object in hastening the removal of the water.

Nevada City.—Thomas Sullivan and William Landrigan are working the old Manzanita hydraulic mine. The deposits of gravel are opened through drifts and are washed by hand.—The Jerry Goodwin property has recently changed hands and preparations are being made to operate.—Good progress is being made in unwatering the inclined shaft of the Idaho-Maryland mine. Lessees working in the upper levels have developed shoots of good ore.

Redding.—The wages of miners and shovelers at Kennett and Winthrop will be reduced February 1, according to the announcement made by the United States Smelting, Refining & Mining Co. at the former place, and by the Shasta Zinc & Copper Co. at the latter. Miners will receive \$4.25 per day instead of \$5, and muckers will receive \$3.75 instead of \$4.50, as at present. Corresponding reductions are made among other trades. Board is reduced from \$1.20 per day to \$1.

COLORADO

Rico.—A. E. Reynolds is unwatering the Emma mine near Duncan, in preparation for drifting on the vein at the sixth

level. Later a raise will be run to the fifth level. Twenty men are employed.

Steamboat Springs.—The Plateau Oil Co. drilling a test on the Chimney Creek structure, 12 miles north-west of Steamboat Springs, has penetrated 18 ft. of the first Wall Street sand. Showings of oil and gas are found but no oil in commercial quantity. The test will be continued to the Dakota sand, the productive horizon of the Rock Creek, Wyoming, field.

IDAHO

Bonner County.—According to I. E. Martin there is only 30 ft. further to cross-cut before striking the vein on the 300-ft. level of the Carpie mine. The vein on the surface near the shaft is about 4½ ft. wide. It is cross-cut at 40 ft., 75 ft., 110 ft., and at 200 ft. On the 200-ft. level there is a 130-ft. drift showing good ore through its length. The vein is 14 ft. wide, with a seam of several inches of good shipping ore, containing copper and silver. The property comprises three claims and a mill-site.

Coeur d'Alene.—The class in geology of Whitworth college, at Spokane, Washington, will make a four-day field-trip to the mining districts of Kellogg and Wallace, January 25 to 28. Fifteen are expected to make the trip. Arrangements have been made with Stanly A. Easton, manager of the Bunker Hill & Sullivan mine, for a thorough inspection of the mine and smelting plant by the students.

Further development work on the 60-ft. shaft in the Pargan mine will be begun, according to L. W. Steadman, manager. It is hoped to add another 300 ft. to the depth of the shaft before summer. When they have sunk 300 ft. more they will have to cross-cut about 200 ft. to reach the vein. Two shifts of miners have started work on the Russel tunnel of the Marsh property to drive it 700 ft. farther, thereby carrying it through the east lines of the claim. This is in pursuance of the recent court order that the Marsh company must show that the vein actually passes out through the east end-line before the court will grant permission for the Marsh people to enter the Hecla workings to raise 700 ft. and demonstrate the identity of the veins.

The Idaho Mines Leasing Co., which has a lease on the ground above the Black Bear No. 3 tunnel, expects to have its new mill running soon after the first of February. The mill will treat 50 tons of ore per day, concentrate to be delivered to the railroad-cars by means of a cable gravity tram.—The Kellogg United Mining Co. has acquired the lease of Savage & Gordon on the old Bunker Hill & Sullivan workings. The transaction includes a flotation plant, which is now being overhauled under the direction of Henry M. Thronson.

MONTANA

Anaconda.—Aluminum has been successfully made at the Washoe Reduction Works. The Anaconda Mining Co. has done extensive work in preparation for the manufacture of aluminum and has effected some economies in the consumption of power.

Basin.—The Obelisk mine-workings are being sampled with a view to developing ore in a mineralized area 300 ft. long, 100 ft. wide, and 400 ft. deep. Samples already assayed are said to show 4 to 15 oz. of silver per ton. Experiments are being conducted to determine the adaptability of the flotation process in treating the ore.

Butte.—The Davis-Daly Copper Co. has curtailed operations at its Colorado mine, where the principal output is copper. At the Hibernia mine, where silver is the principal metal, the production of 200 tons per day will be maintained. During December, 107 cars of 18-oz. ore were shipped, netting the Davis-Daly approximately \$1 per ounce for the contained silver.

Deer Lodge.—Application has been made by the Butte-Jardine company to build a six-mile power-transmission line to furnish power for the new Champion mill, which is now nearing completion.

East Helena.—The Oregon Short Line R. R. Co. has been granted permission to reduce rates on slag from Melrose to the A. S. & R. smelter.

Elkhorn.—The Boston & Montana Development Co. is reported to have purchased 20 carloads of mining machinery for equipping the first section of a 3000-ton concentrator to be erected during the coming year. Included in the equipment are two No. 7½ Telsmith gyratory crushers, four 8-ft. by 48-in. Hardinge conical ball-mills, Wilfley tables, and Janney flotation machines. About 200 men are now employed at the property and a million tons of silver-copper ore has been blocked-out.

Marysville.—Two carloads of gold ore have been shipped from the Bell Boy mine recently acquired by the Philadelphia Mining Co. Specimen samples from the vein are said to be exceedingly rich.

Meagher County.—The old Cumberland mine, last operated in 1893, will be re-opened in the spring, according to H. G. Klenzie. It is said that 40,000 tons of ore is blocked-

out between the 200 and 300-ft. levels, which, with lead selling at 6 or 7 cents and silver at \$1, is estimated to be worth \$2,000,000. A slag-dump from an old 100-ton smelter at the mine will also be shipped.

Nelhart.—A reduction of 20% in the present freight-rate on ore valued at \$25 per ton has been authorized. This should stimulate production for shipment to the smelter at East Helena.

Arrangements have been made whereby the Cascade Consolidated Silver Mines Co. will lease and operate the old Cascade mines. The lessee will operate the Broadwater and Moulton groups, agreeing to perform a certain amount of development work each year. During the first six months the leasing company will pay a royalty of 10% of the smelter returns, this rate to be increased gradually until the royalty is 25% during the third year.

Saltese.—The drift on the 800-ft. level of the Tarbox mine has been extended 190 ft. to the east. A cross-cut is to be run to the big South vein from the 200-ft. point.

LEACHING-VAT AT THE PLANT OF THE NEW CORNELIA COPPER CO.

NEVADA

Cactus.—The Cactus Nevada is to resume work soon, according to Sol Camp, superintendent, who since the closing of the Cactus has been devoting his attention to the Arrowhead Rico lead-silver mine at Ubehebe.

Elko.—The Catlin Shale Products Co. is employing 35 men in the production of gasoline, paraffine-wax, ammonium sulphate, and producer-gas on a large experimental scale. The company has spent several hundred thousand dollars in sinking a 400-ft. shaft on a 5-ft. vein of shale and erecting its plant. The shale will yield 50 gal. per ton, according to present estimates.

Eureka.—Some of the machinery already installed in the Eureka-Holly mill has been turned over. The necessary material for the completion of the mill has arrived and construction will be completed within a month. High-grade ore is being shipped to the smelter.—Ore is being extracted from the shale raise of the Eureka-Croesus and from No. 7 winze. No. 2 raise is supplying some shipping ore, while the drift from No. 8 winze is in limestone impregnated with iron oxide.

Goldfield.—Ore that has been persistent for 20 ft. in a raise from the intermediate level 80 ft. above the 365 of the Great Bend indicates the opening of the ore-shoot for which a long and costly search has been made. The ore assays \$35 to \$70 over a 4-ft. width and it is being saved for shipment. Seventeen leased blocks are being developed in

the Consolidated, according to A. H. Lawry, general superintendent.

Pioche.—An agreement has been made by the Prince Consolidated Co. whereby 100,000 tons of tailing from Bullionville and Dry Valley will be treated in the company's mill. E. R. Richards has made numerous changes and additions to the old Prince Consolidated mill and will treat 100 tons per day with a process especially developed for the purpose.

—Machinery for the development of the Nevada Horn-silver property in the Fairview district is being delivered preparatory to work financed by the Prince Consolidated Co. —The Crystal Silver Mines Co. shipped 1200 tons during the last month.

Pioneer.—The Mayflower has levied assessment No. 6, at the rate of 1c. per share, delinquent March 1. A statement accompanying the notice of assessment shows that since April 1920, when W. J. Tobin resumed the management, the indebtedness has been reduced from \$18,000 to \$10,000. The previous assessment was levied May 18, 1920, and there was received from this \$15,520. Changes have been made in the mill, the principal one being to permit the re-use of water. Settling-tanks have been built below the mill and the water will be pumped from them.

Virginia City.—The Consolidated Virginia company milled 17,706 tons of ore during 1920, with a total net proceeds of \$259,886. —The Comstock Silver Co. is prospecting the Sheels group of claims recently purchased. A drift on the 150-ft. level has exposed ore averaging \$35 per ton.

SOUTH DAKOTA

Deadwood.—There are 1864 men on the payroll of the Homestake company. This force will probably be increased when grading of the site for the new milling plant is undertaken. The new plant will include heavy stamps and ball-mills for crushing, and will have a capacity of 2000 tons per day. It is expected to be ready for operation by autumn.

UTAH

Alta.—During the fiscal year ending September 30, 1920, the Emma Silver Mines Co. shipped 1484 tons of ore, the receipts from which were \$49,657. The company obtained \$7130 from the sale of 100,000 shares of treasury stock. The total receipts for the year were \$59,390. The total expenses during the year were \$101,716, of which \$51,207 was for wages and \$13,499 for mine supplies. The deficit for the year was \$50,999, and the cash balance October 1 was \$49,125. During the period development work totaled 781 ft. of drifts, cross-cuts, and raises, and 671 ft. of diamond-drilling. The ore produced came from a point below the 300-ft. level in the Bay City shaft. Drifting is being done on the Bay City level on what is known as the Phoenix fissure in ground heretofore not prospected.

Bingham.—The United States Mining Co. is now the heaviest shipper among the underground mines in this district, a daily output of 500 tons being shipped. —The Utah Consolidated Mining Co., formerly a heavy producer, has been curtailing production of late and now has but 200 men on the payroll, as against a normal force of 500. —The Utah-Apex company has ceased shipments of ore, and is doing a limited amount of development work.

MEXICO

Cananea.—Following out its policy announced a month ago, the Cananea Consolidated Copper Co. has shut-down its mines, mill, and smelter; 2000 employees, mostly Mexicans, are thrown out of work. They are going farther into the interior of Mexico instead of flocking to the United States where the opportunities for obtaining work are not good. The period of suspension will depend largely upon improvement in the copper market.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

L. C. Graton is in Peru.

Francis Drake has returned to London from Australia.

Charles F. Law, of Vancouver, B. C., is in San Francisco.

E. W. Skeats sailed from San Francisco for Melbourne on January 25.

Howard D. Smith was here last week on his way from New York to Nevada.

Veleair C. Smith has moved from Elizabeth, New Jersey, to Tuxpam, Vera Cruz.

N. H. Darton has returned from Mexico to his work on the U. S. Geological Survey.

M. R. Valentine, formerly with the Portland Gold Mining Co., is in San Francisco.

Clyde A. Heller, of Philadelphia, was in San Francisco this week on his way to Nevada.

Herbert S. King is now superintendent for the Chandler Mining Co., at Ely, Minnesota.

J. M. Callow has returned to Salt Lake City after spending some time at Superior, Arizona.

Arthur Dickenson and **R. H. Conran** are inspecting gold mines in the State of Goyaz, Brazil.

Henry C. Perkins has been chosen a member of the advisory board of the Super-Power Survey.

L. B. Carpenter and **W. S. Larssen** have removed their offices to the Balfour Bldg., San Francisco.

C. F. Courtney, mining engineer to the Sulphide Corporation, at Broken Hill, Australia, is in London.

C. S. T. Farish is assistant mine superintendent for the Amparo Mining Co., at Etzatlan, Jalisco, Mexico.

J. Benjamin Parker has become flotation metallurgist for the Bunker Hill & Sullivan Mining & Concentrating Co.

P. J. O'Gara, plant pathologist of the Utah department of the A. S. & R. Co., has returned from a trip to Washington, D. C.

E. Hogan Taylor, formerly at Great Cobar, has been appointed manager for the New Guinea Copper Mines Co. in Papua.

Theodore Pilger, of Butte and the North-West, has taken a position in the New York sales office of the Allis-Chalmers Mfg. Co., at 50 Church St., New York.

Fred J. Pack, Professor of Geology in the University of Utah, is giving a series of lectures on petroleum geology at the Commercial Club in Salt Lake City.

J. J. Lillie has resigned as superintendent for the Horn Silver Mines Co., to become assistant professor of geology in the Colorado School of Mines, at Golden.

Joseph F. Merrill, director of the School of Mines and Department of Engineering at the University of Utah, has been appointed consulting engineer of the Salt Lake district for the U. S. Bureau of Mines.

Harold A. Linke has accepted the appointment as chief field-engineer on construction work, including mills, mining plants, tramways, etc., for the Compania de Real del Monte y Pachuca, at Pachuca, in Hidalgo, Mexico.

Obituary

A memorial service in honor of **Chester A. Thomas** will be held in the chapel of Stanford University on January 30.

A. L. B. Germain-Griffith was killed in a motor accident at Los Angeles on January 8. He was a British mining engineer and held a military commission during the Boer war. During the recent war he served with the Red Cross.

NOTES 177

THE REPARATIONS 179

The sum fixed by the Supreme Council of the League of Nations appears tremendous. Is it punitive or only just? What Germany would have done to the Allies if she had won the War.

THE GUGGENHEIMS AND THE SMELTING INDUSTRY 179

The origin and rise of this commercial dynasty. Meyer Guggenheim, an immigrant boy from Switzerland. How he first got into mining at Leadville and how he obtained his first foothold in the smelting industry at Denver. The formation of the American Smelting & Refining Co. How the Guggenheims stayed out and then swallowed the so-called trust. The story of their expansion. A criticism of their methods.

DISCUSSION

PROSPECTING IN CANADA

By Charles A. Bramble..... 183

Some of the advantages and disadvantages of prospecting in Canada. Sundry words of advice.

NEW TYPE OF OIL-FIRED ASSAY-FURNACE

By Eric K. Craig..... 184

An improvised furnace and burner for using oil instead of gasoline.

ARTICLES

METALLURGICAL METHODS AT RIO TINTO

By Courtenay De Kalb..... 185

Details of the cementation process. Fundamental facts concerning leaching of Huelva ores. Historical review of the metallurgy of the district. Many of the refinements in the early cementation process have been found unnecessary. Building the heaps. Necessity for ventilation. Shrinkage. The com-

pleteness of extraction is remarkable. Precipitation of copper-bearing solution on iron. Speculation as to cost of producing copper.

TEACHING ENGINEERING STUDENTS TO WRITE

By Homer A. Watt..... 192

The teacher of technical English resembles a drill-master. Three different systems for teaching composition; the elements of each. How technical editors may help.

THE FAIRHAVEN SILVER-LEAD DISTRICT, ALASKA

By Lewis A. Levensaler..... 195

An isolated mining district on the Seward Peninsula. Topography of the country; geology of the region and the occurrence of the ore. Economic features.

CANADIAN MINING IN 1920..... 197

Statistics of production during the past year. The year has been a good one. Copper, zinc, nickel, and coal all showed an increase over 1919.

KARL EILERS V. GUGGENHEIMS..... 199

Mr. Simon Guggenheim's letter to the stockholders of the A. S. & R. Co. in which he denies and attempts to refute the charges of Mr. Eilers. Figures to show the success of operations since 1902.

METAL PRODUCTION IN NEVADA..... 200

A review of the year 1920. The production of all major metals but gold increased. The latter decreased 21%.

THE MARCY ROLLER MILL

An Engineering Product

This mill carries 18 tons of rods or rollers, $3\frac{1}{2}$ -in. diameter and smaller. All crushing is done by rolling action.

In order to carry this rod mass effectively and economically, the best material and engineering design enters into the construction of the Marcy Roller Mill.

The particular MARCY ROLLER MILL illustrated above is designed for large and important installations. We recommend personal investigation as to its operation. Salesman's talk is one thing—personal investigation is another.

Write us and we will tell you where you or your representative will see these mills in operation.

T. A. RICKARD, Editor

WE take pleasure in announcing important changes in our editorial staff. The Editor now enjoys the valued co-operation of two Associate Editors, Messrs. Arthur W. Allen and Arthur B. Parsons. A little more than a year ago Mr. Parsons came to us from Montana, where he had been working as engineer on the staff of the Butte & Superior Mining Company. He is a native of Utah and a graduate of the Utah School of Mines. Our readers have already made his mental acquaintance by means of the special articles contributed by him recently and they will be glad to learn that he is finishing a series of articles on the history and operations of the Nevada Consolidated Copper Company. Mr. Allen has just arrived from Chile by way of London and New York. He was born at Plymouth, England, and was graduated from Cambridge. Since then he has engaged in travel, mineral exploration, and management in many countries, including the United States, Australia, Mexico, Uruguay, Rhodesia, Argentina, and Chile. He leans to the metallurgical side of mining engineering and has won a place already as an author on ore-dressing.

It is proposed to bring coal from Spitzbergen to Canada. The suggestion makes a call upon one's knowledge of geography. The coal will be brought by sea around the southern end of Greenland, across Davis Strait, to James Bay, a southern pocket of Hudson's Bay, thence by rail to Lake Nipissing, and from there by coal-boats to Lake Huron, and so to the market. Spitzbergen now belongs to Norway, we believe, as it should, that country being the nearest neighbor.

HOW gold comes and goes on the ebb and flow of the tides of commerce is suggested by the imports and exports of the standard metal. In 1920, according to the Federal Reserve Board, the stock of gold in this country was increased by \$106,600,000, as against a net loss of \$91,700,000 in 1919. Imports of gold amounted to \$28,700,000, while exports were \$322,100,000. Of the imports, no less than \$274,000,000, equivalent to 64% of the total, came from Great Britain, whereas of our exports 60% was consigned to Asiatic countries.

FURTHER legislative action in favor of claimants under the War Minerals Relief Act is indicated by the passage of a resolution in the Senate calling upon the Secretary of the Interior for detailed information con-

cerning operations under the Act. Senator Robinson, of Arkansas, who introduced the resolution, stated that a construction had been placed upon the law that has the effect of denying most of the claims presented and he desired the further information in order to remedy the miscarriage, if the Senate thought it desirable to take further steps.

NEW MODDERFONTEIN, the world's premier gold mine, on the Rand, produced 968,500 tons of ore, yielding 499,786 ounces of gold, in the twelve months to June 30, 1920. The value of the gold was £2,555,466 and it cost £1,061,622 to produce it, so that the operating profit was £1,493,844. Of this profit £460,000 was due to the so-called premium on gold. The working cost increased to 21s.11d., say, \$5.25, per ton, as against 20s.2d. in the preceding fiscal year. The reserve of ore underground is estimated at 8,869,700 tons averaging 8.4 dwt. per ton over a stopping-width of 67 inches.

NORMAL business is predicted for April or May, and the prophet is no less a person than Professor Charles J. Bullock, chairman of the committee on economic research at Harvard. This committee has done work that commands respect and confidence, so we take the prediction seriously. The same authority says that we would have suffered the worst panic in our national history but for the Federal Reserve system and the fact that Europe was our debtor to the tune of fifteen or twenty billions. Professor Bullock concludes that "we now appear to be in the last phase: liquidation of retail prices and labor".

REFERRING to the proposed bonus to ex-soldiers and other efforts to assist those who did their duty during the War, we note a good deal of false sentiment, as, for example, the custom in the daily press of mentioning every man that wore uniform as "a hero of the world war" or "a war veteran", even when he is under arrest for crime. Meanwhile we note the large number of able-bodied young men behind cigar counters and shoe-blackening stands, all of whom could be spared for more virile jobs, leaving a place for crippled soldiers. It seems to us that the cigar-stands of California should be set aside as employment for invalided soldiers, because they call for no physical strength and no particular knowledge of the goods sold. Most men choose their own cigars. If the talk about helping "our heroes" that are disabled were

sincere, it would be possible to find plenty of jobs for them and to send a large number of husky idlers to real work, instead of allowing them to hang around and play small politics in our cities.

SINCE 1792 the United States Mint has coined 3427 million dollars worth of gold pieces. The Treasury holds 250 million as coin, 400 million is accounted for by the gold-settlement fund of the Federal Reserve Bank, and 500 million is in current circulation. The remainder either has been melted for use in art-work and for industrial purposes, hoarded, lost, or re-melted by the Government into bullion. American eagles and half-eagles are a favorite form of gold for the manufacture of the jewelry with which millions of Chinese decorate their persons; but probably the greater part of the unaccounted two billions has been re-melted at the Mint.

OIL produced in all the countries of the world last year amounted to 650 millions of barrels, as compared with 551 millions in 1919 and 514 millions in 1918. Of this increase, 70 millions is credited to the United States and 60 to Mexico, their joint increase being offset in part by the decreased output of the European oilfields. The combined production of the United States and Mexico was 590 millions of barrels, or about 90% of the world's total. Of Mexico's production, 105 million barrels was exported to the United States, so that 555 million barrels, or 85% of the world's output, was marketed in this country.

NONSENSE often masquerades as wisdom, especially in economics. We read in a report of the well-known Vickers company in London that the chairman, Mr. Douglas Vickers, said the wages paid during four years amounted to 46 millions of pounds sterling, whereas the dividends amounted to only $5\frac{1}{2}$ millions, "that is", added Mr. Vickers, "the workmen received about nine times as much as the shareholders. . . . We have, however, good hopes for next year". We have read similar comparisons elsewhere; they mean apparently that the return on capital invested should be much larger in comparison with the wages paid to the workers. In all such glib statements it seems to be overlooked that wages represent compensation for work performed and that most of the sum is spent in the cost of living. The real question is not whether the workers received more or less proportionately than the shareholders, but did the wage-men perform their work efficiently, that is, honestly and sincerely. If they did, then they deserved what they received. A profit of $5\frac{1}{2}$ on an expenditure of 46 represents $11\frac{1}{2}\%$, which is not bad during a period when the lives of good men were being sacrificed freely for a great cause.

PULVERIZED coal will be introduced as a fuel in the metallurgical plants of the Michigan copper industry within a couple of months. The plant nearing completion at the Michigan smelter of the Calumet & Hecla company will be the first of its kind in that region, but its successful operation will, we presume, be followed by

the general use of pulverized coal. The fuel bill of the copper companies is immense and the increased cost at the coal mines has made the need for economy more pressing. A saving of 35% in the coal consumed has been obtained at other plants and this doubtless can be duplicated in Michigan. The advantages of firing with powdered fuel, aside from the more complete and efficient combustion, are ease of regulation, and flexibility and convenience of operation. The heat units in a ton of coal can be applied where they are wanted, instead of being dissipated in the atmosphere. It is estimated that 16,000,000 tons of coal was pulverized in the United States for use in sundry industries during 1920. The manufacture of portland cement, the iron and steel industry, and the smelting of copper and lead ores account for most of this consumption. At smelters the firing of reverberatory furnaces with powdered coal has been practised for a decade, while more recently a plan has been successfully developed for replacing a large proportion of the coke in the blast-furnace charge by using pulverized coal. At the United States company's smelter at Midvale a particularly effective method of introducing the coal in powdered form at the tuyere-zone of the lead blast-furnaces is employed, the ingenious mechanical equipment being devised by members of the smelter staff. Thus far comparatively little has been done toward operating steam-boilers for the generation of electric power with pulverized fuel; but in plants sufficiently large to justify the rather costly pulverizing equipment, the economy should be important. Rapid expansion in this respect may reasonably be expected. Until recently it was believed that only bituminous coal, with a high volatile content, was suitable for use in pulverized form. However, experiments on mixtures of Western bituminous with other grades of coal have demonstrated the possibility of utilizing anthracite culm, low-volatile bituminous, sundry grades of anthracite, and even coke. We understand that a practicable scheme for using steel tank-cars, for distributing the fuel after it has been pulverized, is being perfected, so that the comparatively small consumer may purchase by the carload exactly as he obtains fuel-oil today. The equipment at his plant would then consist only of the blowers, feeders, and mixers, in addition, of course, to the burner itself, which is ordinarily a simple iron tube into which the dust is injected from a small nozzle in a current of low-pressure air.

THE State Department at Washington and, we understand, the British and French authorities, have invited the attention of the Mexican foreign office to the recent decision of the Supreme Court of Mexico denying relief to the Compañía Minera de Naisa in the litigation whereby the company sought to have reversed the decision of the lower courts awarding the ownership of the rich Maravillas mine in Chihuahua to the heirs of D. Santiago Stopelli, one of the original owners of the property. The interest of the foreign governments lies in the fact that much of the stock in the company is owned by American citizens and British subjects. Apparently pub-

lie opinion in Mexico is not unanimous as to the equity of the recent ruling; the current number of the 'Boletín Financiero y Minero de México' concludes an article apropos of the subject with this remark, as translated by our correspondent in Mexico: "The affair has reached such a delicate point as to make everyone believe that there will be a re-consideration of the decision of the Supreme Court, in all lights defective according to general feeling". This journal gives a review of the history of the mine, the salient points of which can be summarized: Stopelli and D. Saturtino Gonzales, both now deceased, formed a company in 1896 for the purpose of exploiting the Maravillas mineral land. Thereupon they enlisted financial aid from Señor D. Aurelio Corral and others. It seems that Stopelli failed to provide his portion of the capital required and his shares were divided among the other stockholders, apparently without his receiving any compensation for the one-quarter interest that he held originally. Six years later, when ore was discovered and the property became valuable, the heirs of Stopelli started suit to recover a quarter interest in the mine; however, a compromise was reached and the heirs accepted ₧30,000 in full satisfaction of all claims, this transaction being duly entered in the public records. Subsequently still richer ore was found and the company prospered to such an extent that the shares were valued at thousands of pesos. In 1918 the present litigation was commenced, the heirs of both Stopelli and Gonzales seeking to recover not only the mine but the operating profits that had accrued during a period of 22 years. In the naive words of the translator of the article already quoted, "to support this new claim, the claimants allege defects in the constituent instrument [referring to the organization in which Señor Corral and his friends participated], and allege many other reasons, which may be esteemed only by those who frame codes, but which divert entirely from the direct and logical line of the facts"; all of which seems to suggest the perversion of justice by technicality, a deplorable practice, we confess, by no means confined to Mexico. The latest advice is to the effect that President Obregon has undertaken a review of the whole affair.

The Reparations

The amount of money that the Supreme Council of the League of Nations has condemned Germany to pay in reparation is staggering: fifty-three billion dollars; more than twice the amount of our National Debt and not much less than that of Germany! To it is added a 12% tax on exports. Surely the penalty is excessive, says our first thought. Whether it be more than she can pay, it is for others better informed on economic conditions in Germany to say. The average man cannot consider the subject without mingled feelings of pity and resentment. We remember that when Germany defeated France in 1871 she imposed an indemnity three times the amount she spent in that war; and it was not reparation, but indemnity, because the war was fought on French soil, like the last. So long as they were victorious the Germans

expected their victims to pay the cost of their onslaught upon civilization; as late as the spring of 1918 their Secretary of the Treasury stated that the Allies would have to pay the bill. Said he: "We will compel them to drag the chain for a hundred years". At the Armistice the German representatives agreed to do several things: one was to return the French military flags captured in 1870; instead they burned the flags. They agreed to surrender their fleet; instead they sank it at Scapa Flow. They agreed to cut down their army to 100,000, and they have 600,000 armed men at this time. They have broken their word right and left. Nor do they show any signs of regret or repentance for the horror they brought upon the world, they—not only their government, which has changed several times, but also the people, who remain unchanged—only regret their failure. Their children are starving by the thousand and American relief has been organized to feed them. We do not war with children, although we have made no peace yet with the German government. The wrong done France, and to Serbia, calls for redress; it calls for justice; but it is supremely difficult to be just without doing violence to the instinct of humanity. If the Germans had shown signs of repentance; if they had given assurance of their sincere repudiation of the piratic policy of their Prussian leaders, it might be easy to be generous. As it is, we expect that those in whose hands lies the fixing of the terms of reparation will impose all "that the traffic will bear", that is, as much as Germany can pay and yet live. It is horrible; but so was the crime that plunged the world into four years of horror. It is well that war should be made unprofitable to all concerned, victor and vanquished alike.

The Guggenheims and the Smelting Industry

The public controversy between Mr. Karl Eilers and the directorate of the American Smelting & Refining Company provokes an inquiry into the origin of the so-called smelter trust and of the Guggenheim family, with which the smelting corporation is so closely identified. The Guggenheim story is typical of the success of able and energetic men in a commonwealth that aims to give an equality of opportunity to all its citizens, even to those newly arrived from overseas. The story starts with Meyer Guggenheim, a poor immigrant boy who came to Philadelphia from Switzerland in 1847. On board ship he made the acquaintance of an immigrant girl, Barbara Myers, who became his wife, and the mother of seven sons, all of whom played a noteworthy part in American industry. Meyer Guggenheim started as a vender of Swiss lace and other textile fabrics. His first participation in mining is said to have been due to an accident. In 1880, by which time he had become affluent, in consequence of innate ability and shrewd use of the chances offered by his adopted country, he obtained part ownership in a mine in Colorado by means of a note of hand on which a friend had been compelled to default to him. The mine was the A. Y. & Minnie at Leadville. According to a more circumstantial version, he was drawn into

this mining venture by C. H. Graham, a Philadelphian, who in 1879 bonded the A. Y. and Minnie claims. Graham had a partner, also from Philadelphia, named George Work; together they obtained a bond on a half-interest in the A. Y. and on seven-eighths of the Minnie property. This bond was for \$8000 and fell due in October 1879. Graham contributed his share of the money needed, but Work was unable to do so and two days before the expiration of the option he relinquished his part of the deal, whereupon Graham made haste to find someone from whom he could borrow the sum necessary. He met Meyer Guggenheim on the street and asked him to lend him the \$4000, to which Guggenheim replied, "If the mine is no good, you will not be able to repay me". Graham had to acknowledge that this was true; whereupon Guggenheim said, "All right, I'll take Work's half-interest, and then if the mine is a failure you won't owe me anything". The money was telegraphed to the Carbonate National Bank, enabling Graham and Guggenheim to complete the deal forthwith. The remaining holdings in the property were held by Samuel Hirsh, of Leadville; the three owners co-operated harmoniously and profitably until the mine-workings passed from the oxidized into the sulphide zone, when the lower grade of the ore, its refractory character, and the high charges for smelting put a crimp in their profits. Disagreement ensued, and Hirsh was asked to set a price at which he would either sell his share in the property or buy theirs. He placed the figure of \$50,000 on his holdings, whereupon Graham and Guggenheim promptly accepted his offer and became sole owners. This was in 1885. They are said to have made more than \$2,000,000 out of this venture. Guggenheim was a man intensively acquisitive of information, keenly observant; he noticed the heavy charges levied by the smelting companies and concluded that this was the better part of the mining business. At this time he had sent his fifth son, Benjamin, to the mine at Leadville in order that he might familiarize himself with its affairs and look after the family interest in the enterprise, which was managed by Graham. Benjamin became acquainted with Edwin S. Holden, who was then at the head of a small smelter, named after himself, at Denver. In 1887 Holden, Arthur Chanute, Malvern W. Iles, and Richard Cline had built this lead-smelting plant, with the backing of Dennis Sheedy and Charles B. Kountze, local bankers. Holden gave Benjamin a position in the office of the smelter and used him as an agent to persuade his father to purchase a block of stock in the company, thereby raising the additional capital that was much needed just then to put the business on a sound basis. Thus Meyer Guggenheim obtained his first foothold in the smelting industry of the United States. Within a year internal dissension caused him to buy Holden and Cline's shares in the Holden Smelting Company, which was then re-organized as the Globe Smelting Company, with Dennis Sheedy as president and general manager, the other principal stockholders being Meyer Guggenheim, Kountze, Iles, and Chanute. Meanwhile Benjamin had maintained his association with Holden

and Cline, and, with his father's financial backing, joined them in building the Philadelphia smelter at Pueblo in 1889. Benjamin devoted all his time to this undertaking and persuaded his brothers to join him. At this period four of Meyer's sons, namely, Isaac, Daniel, Murry, and Solomon, were engaged in their father's lace business at New York and Philadelphia. Upon Benjamin's insistence that there was more money in producing bullion than in manufacturing lace, they decided to make the change and went to Colorado to familiarize themselves with the new undertaking. The father had succeeded so well in his lace business that he did not care to attend to his smelting interests, which he transferred to his sons under the name and title of M. Guggenheim's Sons, but he continued to be a member of the firm for many years thereafter. He died in 1905. The seven sons, in order of age, were Isaac, Daniel, Murry, Solomon, Benjamin, Simon, and William. All of them, in due course, became participators in this great industrial adventure. The leadership was taken not by the eldest son, Isaac, but by the second, Daniel, who proved himself a man of remarkable energy and sagacity. The brothers decided to extend their operations into Mexico and in 1890 they built a lead smelter at Monterrey and five years later a lead and copper smelter at Aguas Calientes. They now had three plants, producing lead bullion and blister copper, so they decided, in 1896, to build a refinery at Perth Amboy, in New Jersey. Up to this time the only mines they owned were the Tepezala, near Aguas Calientes, and the Reforma, near Monterrey. Later they secured a lease on the Encantada mine in the Sierra Mojada. They were now an important smelting consolidation and were rivals of the first big smelting combination, namely, the one identified with the Omaha & Grant Smelting & Refining Company, the leaders of which were Guy C. Barton and E. D. Nash, of Omaha, together with Edward Eddy, W. H. James, and James B. Grant, all of Denver. In 1897 this group had bought the San Juan smelter at Durango and they were working in harmony with A. B. Hanauer of the Hanauer smelter at Salt Lake City. They owned a smelter at Denver, and both a smelter and a refinery at Omaha. The Guggenheims were a thorn in their side, chiefly on account of the business done by the Philadelphia plant, at Pueblo. On April 4, 1899, a comprehensive consolidation was effected in the name of the American Smelting & Refining Company, under the leadership of Nash, of the Omaha & Grant company, and of Barton Sewell, president of the United Smelting & Refining Company, which owned the National refinery at South Chicago, a lead smelter at East Helena, and the Great Falls smelter. Another influential man was August Meyer, who brought the Kansas City Smelting & Refining Company into the combination, this last company owning smelters at Kansas City, Leadville, and El Paso. In addition there were included the Globe smelter at Denver, the Pueblo and Colorado smelters at Pueblo, the American and Bimetallic plants at Leadville, the Pennsylvania and Germania smelters at Salt Lake City, and the two plants of the

Aurora Smelting & Refining Company, one in Illinois and the other at Leadville. The chief factor in bringing this big deal to a consummation was Frank A. Underwood, who was backed by the brokerage firm of Moore & Schley, in New York. The new corporation became known at once as the 'smelter trust'; it was regarded by the mining industry as a menace that could only be mitigated by the competition of the Guggenheims. The A. S. & R., as the 'combine' was called, asked the Guggenheims to 'come in', offering them \$11,000,000 for their properties, but they demurred to the prospect of playing second fiddle. The truth is that the smelting consolidation, like most affairs of its kind, included a large proportion of dead wood. Of the many smelting plants embraced in the deal, only three or four were earning any appreciable profit, several were losing money, and their owners were in a tight place. As soon as the consolidation was effected, there was a desire on the part of sundry big stockholders to realize upon their holdings, and to do this conveniently it was imperative that the control of the Western smelting industry be made complete by including the Guggenheims, because the merger would warrant the boosting of the shares and the unloading of them on the public. All this was done in due course. The negotiations with the Guggenheims were continued until finally they agreed to accept one-third of the stock in the American Smelting & Refining Company in exchange for their properties; but in the meantime they had purchased, on the open market, somewhat over a sixth of the stock of the company, so that they controlled over a half; and at the first stockholders' meeting, instead of the American Smelting & Refining Company swallowing the Guggenheims, as the newspapers reported, it was found that the Guggenheims were in the saddle and had absorbed the American Smelting & Refining Company. In 1902 the Murray plant at Salt Lake City was completed, taking the place of the Germania, which was dismantled. Some competition still survived on the Pacific Coast, so in 1905 the smelters at Selby, near San Francisco, and at Tacoma, Washington, were acquired in the name of the American Smelters Securities Company, a subsidiary of the A. S. & R. formed at that time as a means for facilitating the expansion of Guggenheim activities. This Securities Company built the Garfield smelter in 1906 and acquired the Velardeña property in Mexico from Guy Barton and James Mathews; it also enabled the Federal Mining & Smelting Company to unload itself, bringing the Everett smelter, which was useless, into the combination. Thus the Guggenheims added the Velardeña and Tecolotes mines to their string. This acquisition of mines by the smelting people was viewed askance by mine operators because through their control of the ore-market the Guggenheims and their associates could make or mar the profitability of a mining enterprise. They were charged with abusing their power, but it is fair to say that we believe the imputation to be untrue. On the other hand, it is safe to say that the Guggenheims would have fared better in reputation if they had stuck to the custom-smelting business instead of branching out as pro-

motors and speculators. Their early success was due, as is usually the case, to the personal character of the men at the head. Of these, Mr. Daniel Guggenheim was chief; he showed remarkable ability and good sense, and he seems to have won the support and co-operation of men of the highest character. The success of the Philadelphia smelter must be attributed in large part to August Raht, a fine metallurgist. The success of the Aguas Calientes smelter and other Mexican operations is credited to Mr. Morse. When the big consolidation was made the Guggenheims acquired the technical services of a notable group of men, including Anton Eilers, the father of lead smelting in the West, who had been identified with the Colorado smelter at Pueblo. With the other smelter at Pueblo they took Mr. William J. Hamilton, one of a remarkable trio of metallurgical brothers, and Mr. W. H. Howard, who is still one of their most valued technicians, as he is one of the most honored men in his profession. With the Perth Amboy refinery they secured the services of Mr. Arthur L. Walker, now professor in Columbia University and a technician whose skill is by no means academic. At the Colorado smelter, at Pueblo, they found Mr. Arthur S. Dwight, the co-inventor of the well-known sintering furnace and a professional man of the highest grade. To these may be added Franklin Guiterman, of Denver, who had mastered the economic phase of Western smelting and was particularly well informed in regard to the sources of ore-supply. Other notable metallurgists in their employ at the time of their early dominance were Charles Livingston, Robert D. Rhodes, George B. Lee, Frank Rhodes, T. S. Austin, H. S. Mulliken, Herman Garlich, Walter Page, Eugene B. Braden, Frank M. Smith, and Karl Eilers, of course, besides E. P. Mathewson, whom they dismissed in 1901 only to re-engage him in after years, by which time he had made a magnificent reputation at Anaconda. Mr. Edgar Newhouse was with the Philadelphia plant as an ore-buyer and he has remained with them ever since, becoming one of the most important men in the organization. Their ore-purchasing department owed much to Mr. Henry Lyne, now retired, who came to them with the Globe smelter, and Mr. H. R. Wagner, who did valuable work in Mexico and South America, and is still an important member of their staff. It is entirely proper, and necessary, to record the names of these men, because without them the Guggenheims would have been nowhere; it was to Mr. Daniel's ability to hold such men that the smelter octopus owed its very life and prosperity. He was willing to pay heavily for experts and he was able to promote cordial co-operation between them and the directors, particularly his brothers, some of whom were by no means as large-minded as himself. In 1916 the firm of M. Guggenheim's Sons was succeeded by Guggenheim Bros., but the change did not synchronize with any increase of fraternal solidarity; on the contrary, it appeared to be one of the results of a suit brought by the youngest brother, William, against his brothers on account of alleged unfairness in the division of the Chuquicamata profits. The new firm of Guggenheim Bros. included only five, for

Benjamin had gone down with the 'Titanic' in 1912 and William was excluded. Benjamin organized the Power & Mining Machinery Company, which bought out the Holthoff Manufacturing Company of Milwaukee and is now one of the constituent companies of the Worthington Pump & Machinery Corporation. He was associated with Messrs. C. E. Finney, Leon P. Feustman, and Cyrus Robinson, of whom only Mr. Feustman remains with the pump company. At the date when Guggenheim Bros. was organized, Daniel was an elderly man, for he was born in 1854; in 1919 he retired and his younger brother, Simon, was pushed into his place as president of the company. Mr. Simon had been long connected with the smelting business of Colorado in particular, and in 1906 he was elected Senator from that State by methods of the crudest kind, provoking derision even among hardened politicians. Unlike his predecessor in office, he had formed strong personal likes and dislikes for members of the A. S. & R. organization, therefore his accession to office was emphasized promptly by a 'shake up', in the course of which several gentlemen found it convenient to make an exit, including the late Judd Stewart, who had created the company's accounting system and was a man generally esteemed. At the same time Messrs. John K. McGowan and Willard S. Morse resigned, as well as Mr. Karl Eilers, with consequences that still echo in the financial firmament.

The third generation has come into the business during recent years. Of Mr. Daniel's sons, Harry is the only one now with the firm; he and Edmund, a son of Murry, are on the executive boards of the Chile Copper Company and the Kennecott Copper Corporation. These young men, of course, were bred amid conditions absurdly unlike those that had helped to develop the thrift and initiative of the founder of this commercial dynasty; they climbed into the circles of *haute finance* and cherished social ambitions, which may be said to have found suitable expression in the marriage, last December, of Mr. Solomon Guggenheim's daughter to Viscount Stuart, the son and heir of the Earl of Castle-Stewart, the sixth in the title.

One phase of the Guggenheim operations we find it difficult to disentangle, namely, the interplay of the subsidiary corporations that they formed for the purpose of their financial operations outside the custom-smelting business. The Guggenheim Exploration Company was formed as early as June 1899, to be dissolved in 1915. The American Smelters Securities Company was organized in 1905. Besides these there is the National Metallurgical Company of Mexico, and, of course, the family firm. By use of these four subsidiaries the controllers of the American Smelting & Refining Company promoted various mining ventures and speculated in the shares. The Guggenheims also are said to have allowed the members of their organization to play the market on personal account. Their abortive deal in a large block of Nipissing stock in 1906 simply showed how easily Capt. De Lamar could outwit them and their engineer. The Yukon Gold issue in 1908 was discredited

by their use of Thomas W. Lawson as an ally. The Cumberland-Ely affair aroused deep resentment. The Chuquicamata issue in 1913 was an example of cynical effrontery, for they sold \$15,000,000 in bonds to the public and took for themselves the \$95,000,000 in stock. The financial legerdemain by which they consolidated the Braden fizzle in Chile with the Kennecott bonanza, in Alaska, was another example of the abuse of their prestige for the purpose of what in South Africa is called 'vernukerij'. This later part of their career as a family and as a firm therefore seems to be open to grave criticism, and even ridicule. Many of the mines they bought proved 'lemons', they missed many good ones; personally they were not adapted for such dealings, although equipped hereditarily for the keen commerce of custom smelting. The original basis of their operations became secondary to the making of money through subsidiary companies and the acquirement of valuable assets for the family firm. In twenty years the holders of common stock in the American Smelting & Refining Company have received an average of less than 4% per annum, while the Guggenheims themselves have waxed exceedingly wealthy. Here we may record the fact that in 1905, soon after the Guggenheims secured control, the common stock was quoted at \$170 per share, as compared with \$29 recently. Mr. Simon Guggenheim's apologia, which we publish on another page, is by no means convincing, despite its array of big figures to indicate the gross earnings of the company. If he would give figures to show how much the common stockholders, for whom he and his brothers were trustees, have made since 1901 and how much he and his associates have made by use of the company's organization since that time, we think the comparison would be odious. The fact is, these big groups or 'interests', as they are called, constitute a sinister phase of finance. Of them it can be said emphatically as was said by Thurlow concerning the corporation in general that "it has no soul to be damned and no body to be kicked". The morale of syndicates is low; it is much lower than that of the individuals of which they are composed. Another induction from the facts is the generalization that it is easier to create super-enterprises than it is to find the super-men to run them successfully. The late Benjamin Guggenheim was smart; Mr. Daniel Guggenheim proved himself extremely able; but Mr. Simon is not the type of man one would select as the head of an immense technical-trade organization such as the A. S. & R. Again the old question arises: Are the directors trustees for the shareholders or are they only privileged speculators? It seems as if the time had come for a re-organization of the executive board of the smelting company, not in the interest of Mr. Eilers or any small group of stockholders, but in behalf of the main body of stockholders, whose property rights are many times larger than the combined shareholdings of the two groups now engaged in what may seem to be only a domestic quarrel. We hope that these inarticulate stockholders will take steps to make themselves properly heard at the annual meeting next April.

DISCUSSION

Prospecting in Canada

The Editor:

Sir—An enquiry from a young engineer, as to where he could find unprospected ground other than Mexico appeared in the 'Mining and Scientific Press' of January, and seemed almost an invitation to write this article. Surely it cannot be realized by American prospectors that an immense territory awaits not only prospecting, but even exploration, north of the boundary between Canada and the United States, otherwise it were difficult to account for the indifference they exhibit.

Here, within a few hours railway journey, is a land where men speak the same English tongue, with but slight variations; where the climate is eminently healthful; where the alien has the same rights as the native; where the apex law does not, happily, obtain; and where the honest-to-goodness prospector, no matter whence he comes, will find a hearty welcome awaiting him.

Without particularizing any region, it may be better pointed out that the whole 'pre-Cambrian shield', that vast territory stretching from the Atlantic verge of Labrador to the mouth of the Mackenzie, holds patches of the two great mineral-bearing formations, the Keewatin and the Huronian, and wherever these have been intruded by later granites or granite-porphyrates, indications, at least, and often much more than indications, of minerals have been discovered. Experienced men believe only that the Canadian pre-Cambrian has hardly been scratched, and is destined to make important contributions to the world's metallic wealth.

There must, surely, be many Cobalts, Porcupines, and Sudburies awaiting discovery. Of course, much of the aforesaid shield is hidden from view by lake, muskeg, or glacial gravel; it is not probable that the last valuable find will be made for many a century, but the prospector of today is fortunate, because the obvious exposures, the veins visible to the first practised eye viewing them, the outstanding lodes against which a man may be halted by the simple process of stubbing his toe, are mostly unskipped. Future generations may have to dig through the cover of glacial debris, they may have to drain swamps, to lower the levels of lakes to find what they seek; but as this is unnecessary; all the prospector has to do is to walk, or paddle, and keep his weather eye open to discover the wealth of the pre-Cambrian rocks.

This sounds easy, does it not? Yet there is a good deal to be attended to. The Canadian bush is not a region full of blood-curdling dangers. Far from it; it is a region of great calm, of almost illimitable distance; of solitude, and during five months of the year almost Arctic

cold. Accidents happen, occasionally, but usually to the tenderfoot, the man who does not know the ropes; rarely to the old hand. The means of travel are the canoe in summer and the dog-train in winter; but during the cold season prospecting may hardly be carried on, seeing that the ground is covered by a mantle of snow, and the intense frost has made gravel-beds as hard to excavate as though they were marble. Underground, however, winter-time is the better for preliminary work, as water does not give trouble and ventilation is easier to arrange than in summer.

No tenderfoot should think of taking to the bush without a 'pard' who has had years of experience, either in Canada or Alaska. Most of the fatalities that have occurred have been due to an overturned canoe, to being caught by a blizzard too far from shelter, or through running short of provisions—and a man's appetite is something phenomenal when traveling through the Canadian wilderness.

Nevertheless, the life is alluring; few healthy young men care for any other after being introduced to it under favorable auspices. Only a couple of summers ago I met a prospector, one of the best we have, who will probably soon bank a couple of hundred thousand dollars as the result of the sale of his share in the Flin Flon copper deposit, north of The Pas, and in answer to my question: "What will you do when you get all that money?" replied: "Do, why just the same as I have been doing for the past dozen years—live in this north country, and, I hope, die here."

But anyone thinking of taking my advice should secure his backing before coming, and also make sure that there is a channel open for the flotation of his find. Canadians do not as a rule, though there are, of course, many exceptions, display that alacrity in providing the sinews of war which are necessary to a campaign; there is nothing like the wealth lying loose on this side of the boundary that there is on the other, and men of moderate means are prone to look with more favorable eye upon a mortgage than a mineral deposit, notwithstanding that the latter may yield a much larger return.

Prospecting is a gamble, say what you will. It is a case of spinning a coin with the fickle goddess: "Heads I win, tails I lose," and this is, perhaps, to some natures its greatest attraction.

As to the cost of prospecting, a precise answer is impossible, so much depends upon the men; but an initial outlay of five hundred dollars for traveling expenses and outfit, and a hundred dollars apiece per month for the seven prospecting months, should be sufficient. During the winter prospectors hibernate more or less, and fifty

dollars per month from November to April ought to liquidate all bills.

One word more: Those who make a success of prospecting are they who run straight. "The Heavens are high and the Tzar far off", as the Russians used to say before the débâcle. The temptation to play fast and loose with backers is more than many can resist, but, putting ethics aside, it does not pay in the long run. A reputation for trustworthiness is quite as valuable to a prospector as to any bank official in the land; each is trusted with the investment of monies confided to his care in the belief that he is an honest man.

CHARLES A. BRAMBLE.

Winnipeg, January 22.

A New Type Oil-Fired Assay-Furnace

The Editor:

Sir—The rise in price, and the increasing difficulty in obtaining prompt shipments of gasoline, are causing concern to assayers in isolated districts. Five months ago the gasoline supply at the Pato mines became exhausted. It being the dry season of the year, navigation on the Nechi river was closed; consequently there was no hope for the arrival of a new supply for many weeks.

High-gravity crude-oil for the Case No. 125 melting-furnace was available, so it became necessary to devise an oil-fired assay-furnace at short notice. A two-inch pipe was teed into the 2½-in. discharge-pipe from the melting-furnace blower with a bushing. This pipe was carried 30 ft. into the assay-room, necessitating two elbows and two 'hot bends'. The burner was constructed by threading a ¾ by 2 by 6-in. home-made nozzle with short nipple into a two-inch tee. Into the opposite end of the tee was fitted a plug through which was tapped a quarter-inch pipe, extending to just short of the nozzle-tip, and protruding half an inch through the plug. A needle-valve was screwed on the protruding half-inch, fitting snugly against the plug. With the oil used, six feet of head gave sufficient pressure at the needle-valve.

The burner was tried with the same furnace that had been used with the gasoline burner; but the furnace, which was a home-made affair of brick and clay, had many cracks, and when the fire was going full tilt it resembled an aurora borealis in miniature. For a new furnace the only material available was three firebricks, plenty of pressed brick and clay, and some extra inner liners for the Case tilting-furnace. Supplies from the United States require from six months to a year for delivery, so, of course, were out of the question.

The new furnace was built to the accompanying drawings. The 'boss' is a 3 by 6-in. graphite crucible cut diagonally to fit the inside of the furnace. A hole was bored through the bottom to take the burner-nozzle. The rear of the muffle was supported by a firebrick cut in two, lengthwise. The door of the fusion-furnace was a firebrick placed on end, and the door of the muffle was made by laying a firebrick on its narrow edge on top of an extra Case liner. The two top bricks in the elevation are loose, and form the damper.

In the first trials of the furnace, feathers would not form on the cupels, although the temperature was scarcely above 'freezing'. Many experiments were made by regulating the fuel, the damper, and the ventilating orifice in the muffle. Only part success was obtained until Mr. Evans' suggestion in your issue of June 26, 1920, was tried. It was found to be the key to successful cupellation in this furnace. By cutting down the air instead of the fuel, we now feather twenty-three 1½-in. cupels in the 6 by 12-in. muffle, with the door wide open.

In a circular furnace of this type no baffles of any kind are required. Both ends and sides of the muffle show an exceptionally uniform temperature. Twelve 20-gm.

crucibles can be fused in the lower part of the furnace at one time. Regulation of the temperature is as close as with the best gasoline burner; and also as quick. The cost of operation is directly proportional to the cost of fuel-oil to gasoline, the consumption being equal.

Oil-fired assay-furnaces have a wide range of operation. With a little patience in starting, and by regulating the air until the draft is from the muffle-door to the ventilating orifice, no operator with an eye to his cost-sheet would ever return to a gasoline-fired furnace.

ERIC K. CRAIG.

Pato, Colombia, August 3, 1920.

Metallurgical Methods at Rio Tinto

Details of the Cementation Plant

By Courtenay De Kalb

*The cementation plant comprises three large areas containing 18,540,000 tons of ore; the ponds with a capacity of 5,540,600 cubic metres; and the precipitation tanks, or vats.

The sulphuric-acid factory consists of four McDougall roasting-furnaces, with a capacity of 20 tons each per diem, two Glover towers of 160 cu. m. each, lead chambers, etc., for a daily production of 50 tons of acid.

On a site near-by is the smelter for the production of blister copper, containing five water-jacketed shaft-furnaces, of 250 tons daily capacity each, yielding matte running from 20 to 25% in the first fusion. In the second fusion the matte is raised to a grade between 40 and 5% copper, which is sent to the converters. The blister copper is cast in iron molds giving ingots of 125 kg., the grade running from 96 to 97%, and another from 97 to 100%. The plant at present is capable of yielding from 15,000 to 20,000 tons of blister copper.

It may be stated that the foregoing outline of the smelting plant by Señor Peña gives an impression that in many respects erroneous, probably because he was not sufficiently familiar with smelting practice in its details to appreciate the excellent work being done by the metallurgical staff of the Rio Tinto company. Having studied all details myself, which unfortunately have not been released for publication, I may say that it is not the practice of the Rio Tinto smelters to make two blast-furnace fusions, as above indicated. In fact, such treatment would be prohibitive on account of the excess of iron that would have to be fluxed, calling for such large amounts of silica, which in part has to be barren on account of certain difficulties presented in trying to use the silicious ores alone. So nearly do the smelting superintendents here depend upon the sulphur in the ore for the heat-requirements of the furnaces that only 1.6% of the total charge of ore and flux consists of fuel added, this being Welsh anthracite instead of coke. Señor Peña's statement as to the grade of matte produced in the first fusion is correct, but evidently he was confused as to the grade of matte going to the converters. This averages a trifle over 20% and naturally this low-grade material calls for considerable expense in blowing, not only with regard to the total volume of air needed, but to the length of time required for each blow, which is necessarily long in proportion to the copper produced,

entailing greater wear and tear, and increased labor. Another explanation would appear to be necessary in regard to the grade of the blister copper, which is quite uniform. The typical analysis is submitted in order to correct the erroneous impression given by Señor Peña.

	%
Copper	98.58
Iron	0.01
Sulphur	0.24
Silica	0.10
Arsenic	0.095
Oxygen	0.05
Gold	0.25 oz.
Silver	19.35 "

With reference to the cementation, Señor Peña's statement of tonnage in the leach-yards is substantially correct. He does not touch upon the leaching practice, since this is in no wise peculiar to Rio Tinto. Indeed, it would appear that the method is so simple, so elementary, that it is incapable of important modification. It is perfectly adapted to the Huelva ores, which does not mean that it is necessarily adapted to pyritic ores in other parts of the world. Nevertheless, skill counts in the results obtained, even with typical Huelva ores, as will appear in the following discussion.

The fundamental facts concerning the leaching of the Huelva ores are the following:

1. The leaching is accomplished by oxidation of the copper sulphides in the presence of moisture.
2. The pyrite is attacked only to a slight extent, even after 15 or 20 years exposure in the heaps. Shrinkage is rarely more than 7%.
3. Successful operation depends upon proper ventilation of the heap more than upon any other single factor.
4. The typical ore as delivered to the heaps contains from 46 to 47% sulphur, and, in the process of leaching, as a result of the removal of the copper and of a small proportion of the iron, the sulphur content is raised to a point between 49 and 50%.
5. The silicious ores, containing calcocite and almost no pyrite, yield their copper almost completely when leached.
6. The pyrite, on being lifted from the leached piles, remains massive and undecomposed, practically as it comes from the mine.
7. Coarse pyrite leaches as readily as, and yields its copper much more completely than, the fine.
8. The major proportion of the copper is leached from the piles in three to three and a half years, the metal recovered in that time being sufficient to return the total

*This article is part of a report made for the U. S. Department of Commerce. The data used are taken mainly from a paper by Javier Peña, in the Boletín Oficial de Minas y Metalurgica of the Ministerio de Fomento, No. 3, August 1917.

operating cost of the mine and leach-yards. The additional copper recovered after this period, as well as the residual pyrite (50% S), apparently represents operating profit.

The process of leaching the ore is known locally as 'cementation'. This method, in some form, has been practised from remote epochs, but never to the extent now in vogue. Richard Ford, an acute but non-technical observer, writing in 1869, makes no mention of it. The method of extraction then in use was smelting, but he does mention the fact that the waters of the Rio Tinto, which partly have their source in the Lago and San Dionysio mines of the Rio Tinto company carried copper in such abundance that it was regularly extracted. "Iron bars are placed", he says, "in wooden troughs, which are immersed in the waters; the 'cascara', or flake of metal, deposited on it is knocked off; the bar is then subjected to the same process until completely eaten away." This contains the germ of the method as practised today; it was logical to imitate Nature in leaching the copper from the ore, and the precipitation of the copper on iron was a reaction that had been known for generations.

Despite Ford's failure to report the leaching method, it is mentioned as having been employed at Rio Tinto since 1839, by Joaquin Gonzalo y Tarin in his 'Descripcion Fisica, Geologica y Minera de la Provincia de Huelva', Madrid, 1888. It may be said in passing that this is one of the most scholarly books ever written concerning the mines of Huelva, and is now exceedingly rare. The subject is also discussed at considerable length by Ramon Rua Figueroa, in his 'Ensayo Sobre la Historia de los Minas de Rio Tinto', Madrid, 1859, a work even more rare than that of Tarin. He refers to the process of cementation as having first appeared in 1752, but it seems from the records that this copper of cementation represented metal merely precipitated from the mine-waters. This was during the administration of Samuel M. Tiquet, who supplanted Liebert Wolters through successful litigation. Cementation is again mentioned in 1788 by Francisco de Angulo, but the references to it do not indicate that artificial leaching was employed, although the practice of heap-roasting and subsequent smelting in reverberatories is specifically described.

A curious discussion took place about this time regarding the properties of cementation copper, that is, copper precipitated by iron, and a prejudice against its use in the trade was created by statements that it was not really copper, but only iron colored by copper. The question assumed such importance that it was seriously discussed by eminent men of the time, and the theory of the process of cementation, or precipitation by iron, was presented with remarkable clearness and accuracy by Pedro Heury, professor of mathematics in the University of Seville, which was printed in the transactions of the Royal Patriotic Society on May 12, 1791.

The application of the modern method of extracting the copper by leaching was the result of investigations made by a Spaniard, Felipe Prieto, of Seville, who obtained a 'privilegio', or royal patent, for the process,

which was published in the Official Gazette on September 9, 1845. It was described as an original invention for "a chemical discovery for utilizing the copper-bearing pyritic minerals, no matter how low the percentage may be". Prieto was an indefatigable worker, and it must be admitted that the establishment of the process on a working basis was due to his energy and determination; but it was by no means the original discovery that he claimed. It was inevitable that the possibility of extracting the copper by leaching would have been discovered accidentally at a comparatively early period, because of the prompt reaction that occurs on exposing the ore to the elements. The earliest mention of the process was in the 15th century, and was made by the alchemist Basilio Valentin in a treatise entitled 'Currus Triumphalis Antimonii'. It was applied on a working scale at the mines of the Lower Harz in the middle of the 16th century, and it was again described in 1640 by Alonso Barba in his work 'Arte de los Metales'. Nevertheless, it appears that these early investigators had not conceived the idea of using the simpler method as worked out practically by Prieto. They seem not to have been able to break loose from the notion of hastening the reactions by heat, and the heaps were first subjected to some degree of roasting. Barba specifies that the ore should be "burned" until the pyrite had lost its brilliancy, after which it was to be leached and the copper precipitated from the liquors by iron.

The important contribution to the technology of leaching that has freed the Huelva mines from dependence upon pyro-metallurgy, making it possible to cover the costs of operation by extracting the copper even from ores leaner than 2%, must be credited to Felipe Prieto. In reality it appears to be a process peculiarly adapted to the character of the ore found in this district, and it has not yet been determined conclusively what the peculiarity is that renders it so suitable. This can be ascertained only by investigations aided by the microscope, a study that still remains to be undertaken. No information that was based upon anything more than shrewd surmise could be obtained from any of the operators at Huelva. The results of the process are extraordinary, not alone because of the extremely high percentage of copper recovered, but because the leaching of the copper does not lead to any extensive disintegration of the pyrite. So far as my own investigation is concerned, which from force of circumstances has been somewhat hasty and superficial, it would appear that the reason may be found in the fact that the copper sulphide was introduced by mineralizing agents toward the end of the deposition of the pyrite, if not entirely subsequent to its formation. The copper appears to exist almost wholly in the form of chalcopyrite and secondary chalcocite following the parting-planes of the pyrite. Only to a slight extent is the copper held as a solid solution in the iron sulphides. There is evidence to show that, in nearly all cases, the original deposits have been subjected to pressures that developed fracture-planes, into which later metal-bearing solutions could readily have pene-

trated. There is no doubt that this has happened.

The method of leaching, as originally applied, is quite fully described by Tarin. This will be of interest to the student, but the practice today has grown far simpler, as skill in the operation has increased. Success is largely a matter of experience. The following notes are the result of information gathered from a number of successful operators in the different parts of the province of Huelva, and by personal study of the practical work, facilitated by data from the records of various plants.

In the beginning it used to be considered necessary to build the piles in a very exact manner, with impervious bottoms of tamped clay, and with carefully walled-up ventilating shafts or 'chimneys' through the pile of ore, and to regulate the entrance of air along the side by covering it with fine which could be opened up at places if desired. Careful observation of the temperature by thermometers was made at frequent intervals. Today most of this old routine is abandoned. No attention is

over the widening pile in ordinary mine-cars of 1000 to 1500-lb. capacity.

The depth of the piles is variable, starting from zero at the up-hill end and terminating below with a maximum height of 32 ft. The coarser the ore the deeper may be the pile. The fine does not afford good extraction; it yields about 50% of the copper promptly, after which the recovery is very slow, and the total extraction is most imperfect. Accordingly, care is taken in blasting at the mine not to produce much fine ore, and the run-of-mine is taken to the leach-piles, with much material as large as 12 to 18 inches diameter. This is in violent contrast with prevalent ideas as to leaching. The ideal usually sought is to ensure intimate contact with an abundance of the lixiviant, and to crush the material preparatory to leaching to a finely granular condition. This is exemplified in the old practice of vat-leaching of gold ores in the cyanide process. It was also formerly thought necessary to follow a similar practice in the

A BED OF LEACHED ORE AT RIO TINTO

SHIFT-BOSS OFF DUTY IN THE SOUTH PIT

paid to the character of the bottom; any ordinary soil is satisfactory; the drainage from the area is so complete as to cause very little loss that can be accredited to seepage into the ground. The topography also is a matter of minor importance. Some of the piles or 'mon-cones' are built around steep hills having a slope as sharp as 15° to 18°. In many parts of the Province the low ground is preferred, probably because the soil contains more clay and is less pervious, but the grade then falls as low as 2° to 4°. The superintendents generally prefer a grade of about 10°. No attempt is now made to build piles of uniform shape. Large areas are covered, being extended down-grade, like a broad dump-pile, with a level surface from the tram-lines that are built on contours to facilitate distribution of the ore. In fact, the most economical transportation of the ore is a controlling factor. An ideal condition is a contour on which the ramway can be constructed and from which there is a harper descent to ground that then flattens again. This enables bins to be built, into which the ore may be lumped from the mine-cars, which usually hold from 10 to 20 tons. From these bins the ore is then trammed

earlier attempts at the leaching of copper ores. More recently, as seen at the Ajo mine in Arizona, the ore is crushed only to about $\frac{3}{8}$ inch, with considerable coarser material going to the vats. The lixiviant penetrates these relatively large ore-particles, resulting in a complete extraction.

The cementation practice at Huelva is wholly different from this. The ore-piles are never immersed in water; they are barely wetted, and are kept wet only a portion of the time. No acid is added, since this is produced in sufficient quantity by the oxidation of the sulphur. Plain water, and also the return-liquor after precipitation of the copper, constitute the lixiviant, although at some mines the spent liquors are returned only in part, or not at all. In the beginning, no water is added. The ground is always moist from the drainage of liquor across the yard, and this moisture rises gradually into the pile; in this manner the ore absorbs the maximum that it will hold until active leaching begins. Some exudation of soluble copper-salts takes place during this initial period, for it must be noted that the ore as it comes from the mine contains sometimes 50% of its copper in the form

of sulphates, and 10% as sulphate is almost always present in the raw ore at the mine.

Fine ore is spread over the top of the piles during this period, partly to regulate the ventilation, and partly to furnish a restraining bottom for the wash-water, so that it may seep downward into the ore with some degree of uniformity instead of washing through it suddenly and ineffectively. This cover of fine is then shaped into a series of low ridges bounding basins, from four to six feet square, arranged for continuous flow from one to another, the quantity of water being adjusted to the rate of seepage so that no overflow occurs from the last basin in each series. It is laid out precisely like an irrigated garden.

While the pile is becoming moistened from below it gradually heats from the oxidation of iron and sulphur. The temperature will rise at spots to 150°, and even 180°F., but this promotes such active oxidation of pyrite that it should be held lower. A new pile begins to heat in four to six weeks without the addition of any water from the top. This temperature is controlled as far as possible by ventilation, the draft of air through the pile being restrained and governed by the covering of fine. On one extremely large pile, covering several acres of ground, which I inspected, the temperature had risen to about 130°F., with spots from which steam and sulphurous gas were issuing, and here the rock on the surface was too hot to be touched. This pile had been begun in February and finished in April. The higher temperature was coming from the April ore. The hot spots were being tamped by fine thrown upon them, and preparations were nearly completed for the first wash. The quantity of water used was too variable to enable me to get any expression from the superintendents of leaching as to the ratio per ton of ore. After a pile has been leached for a long period it becomes less active, less liable to rapid oxidation, and requires less frequent washing. There is no stated time-interval between successive washes, this depending altogether upon the condition of that pile as to temperature. During the rainy season the piles stay wet a large part of the time, and the tendency is to over-dilute the solutions. During the summer the quantity of waste-solution to be handled is materially reduced. At one plant that I inspected, the area of heaps must have embraced about 600 acres. The maximum flow of solutions from this area, which flow is measured at a weir above the precipitation-plant, is 550 cubic metres per hour, or 13,200 cu. m. per diem (3,442,878 gal.). This amounts to a per-diem average of approximately $7\frac{1}{2}$ gal. per square foot of surface, although I am sure that the superintendent would say that any average is misleading. The flow at times drops to 380 cu. m. per hour from this same area. The ore absorbs from 3 to 10% of its own weight of water when the piles are first laid, and after leaching and drying it will take up from 10 to 12% of water.

On giving a pile its wash it always settles, but this is generally less on the first wash than on the second. Sometimes, if the temperature has crept too high, it will settle

18 inches or more, which indicates that there has been excessive oxidation, causing disintegration. The temperature follows up the incline of the heap from the lower (and deeper) edge. Thus it can be watched and gauged with considerable accuracy. Excessive shrinkage of a heap means poor management, as a rule, though in part it may be due to an excessive amount of fine in the material sent to that heap from the mine. As the tendency of the ore in certain places in the mines is to produce more fine than in others, it becomes necessary for the foremen at the mines and in the leach-yards to work in close agreement through the yardmaster to deliver coarse and fine ore in suitable proportions to the various parts of the leaching plant while building the heaps. The shrinkage cannot be expressed in volume, but by weight. As determined from some of the larger heaps, it amounts to about 17% by weight. The average through years of experience seems to be 7%, but with 3% of copper present in the ore, shrinkage will be 15 to 17%. In some places the average shrinkage is as much as 10%. This does not include mechanical losses in removing the leached pile, and in screening for market. The total losses amount to more nearly 20% of the ore laid down in the leach-yards.

Figures were hard to obtain concerning the amount of pyrite lost in the process. It would require the collection of data for a long period, with this object in view, to reach a reasonable conclusion upon this question. The average analysis of the ores compared with the analyses of leach-liquors shows that many other elements besides iron figure in the reduction of weight. For example, the zinc leaches as readily as the copper, but it does not precipitate in the vats, hence it would seem that it re-deposits on the ore. Arsenic represents a considerable amount of weight removed; as minor factors, phosphorus, tin, and lead are leached and are precipitated from the solutions. The analyses at hand are insufficient to explain what actually happens. Many of the substances dissolved build up in the return-liquor, and should continue to do so until a much higher density of solution is reached, unless there is a constant elimination of spent solution at an equal rate with the introduction of fresh water into the leach-cycle. There must, consequently, be some escape, accidental or otherwise, for the spent liquors, to account for the reduction in weight. This is rendered all the more necessary when the high rate of evaporation during the long dry hot season is considered, in which period high concentration of the solution would occur unless large additions were made, sufficient to compensate not only for loss of water by evaporation but for loss of solution rich in salts. The spent liquor is all returned to be applied as part of the wash upon the heaps. The specific gravity of the solution remains constantly near 1.1. The iron in the spent liquor ordinarily amounts to 20,000 parts per million, this including both ferrous and ferric sulphate. A large part of this iron is derived from the solution of the chalcopyrite, so that the pyrite itself, to that extent, is not robbed. Despite the fact that chalcopyrite films are easily detected in apparent

abundance on inspecting the ore by the eye, the verdict of the cementation superintendents is that the copper present is mainly in the form of 'black copper'* and chalcocite (Cu_2S), in nearly equal amounts. CuS does not require the presence of iron sulphide to facilitate its solution, as it will oxidize directly. Therefore, the extraction depends upon maintaining a sufficient amount of air in circulation. If the oxygen is insufficient a reaction occurs between the water (as water vapor) and the sulphur, producing sulphuretted hydrogen, which serves as an indicator. The reaction is

The question as to what series of reactions occurs in the heap is still a matter of dispute. The chemists in charge accept the following well known series of formulae as probably expressing the phenomena that occur:

- (1) $33\text{FeS}_2 + 28\text{O} + 4\text{H}_2\text{O} = 29\text{FeS}_2 + 4\text{FeSO}_4 + 4\text{H}_2\text{SO}_4$
- (2) $4\text{FeSO}_4 + 4\text{H}_2\text{SO}_4 + 2\text{O} = 2\text{Fe}_2(\text{SO}_4)_3 + 2\text{H}_2\text{O} + 2\text{H}_2\text{SO}_4$
- (3) $\text{Cu}_2\text{S} + \text{Fe}_2(\text{SO}_4)_3 = 2\text{FeSO}_4 + \text{CuSO}_4 + \text{CuS}$
- (4) $\text{CuS} + \text{Fe}_2(\text{SO}_4)_3 + \text{H}_2\text{O} + 3\text{O} = 2\text{FeSO}_4 + \text{CuSO}_4 + \text{H}_2\text{SO}_4$ or
- (5) $32\text{FeS}_2 + \text{Cu}_2\text{S} + 3\text{H}_2\text{O} + 33\text{O} = 29\text{FeS}_2 + 2\text{CuSO}_4 + 3\text{H}_2\text{SO}_4 + 4\text{FeSO}_4$

In the opinion of some operators the amount of soluble copper (as original sulphate) in the ore as received from the mine is about 0.5% and sometimes as high as 1%. This latter would be half of the average copper-content. This unquestionably differs in different orebodies, and is to some extent dependent upon whether there is free drainage or not from the mines. If there is not, then the amount may become large. At Rio Tinto the ore from the San Dionysio mine contains largely secondary copper sulphides, and this mine has natural sub-drainage flowing into the Rio Tinto. The old Rio Tinto south lode seems to have more sulphate, and this mine apparently contributed less to the river-drainage. The chalcopyrite, in leaching, is probably removed through the solvent effect of $\text{Fe}_2(\text{SO}_4)_3$ upon that mineral. This then robs iron, to some extent at the expense of the pyrite, in becoming reduced to FeSO_4 .

The completeness of extraction is remarkable. After ten years exposure the copper is almost wholly removed. I am assured that the extraction exceeds 95%. After three years the upper six to eight feet of a pile will show an extraction of about 80% of the original copper; the next six to eight feet, 60%, and so on to the bottom. Time is an important factor in leaching. Huelva pyrite will yield some copper after a pile has been leaching 30 years or more.

For successful leaching, alternation in the application of wash-water is a matter of great consequence. The water must be so adjusted as to descend very slowly and wet the pieces of ore, giving time for deep penetration by capillarity. It must then be allowed to dry so as to draw in oxygen to facilitate and complete the re-

actions. The removal of the copper, some zinc, a portion of the iron, with other elements, results in elevating the original sulphur-content of 46 to 47% in the raw ore to 49 or 50% in the washed ore. No difference is observable to the eye between the two. The washed ore appears as bright and fresh as when it came from the mine. Some basic iron sulphate deposits around the sides and on the top of the heap, but not on the ore within the pile.

The following analyses represent approximate averages of the solutions entering and those leaving the precipitation vats, the quantities being stated in parts per billion:

Analyses of Solutions in Cementation

	Entrada	Salida
Ferrous iron.....	19,215	23,250
Ferric iron	1,464	none(?)

IN THE TOWN OF PUEBLA DE GUZMAN, NEAR THE THARSIS MINE, SHOWING A GROUP OF PEASANTS

Copper	3,483	23
Zinc	1,978	2,100
Arsenic	230	78
Antimony	2.1	none
Bismuth	2.3	1.3
Cobalt	13	10
Manganese	59	118
Silica	180	268
Calcium	230	252
Alumina	539	1,003
Magnesium	284	234
Potassium	402	314
Sodium	300	228
Phosphorus	31	8
Tin	11	3
Lead	8	1.8
Chlorine	43	39
Total SO_4	59,206	55,536
Free H_2SO_4	8,582	4,260
Specific gravity	1.0820	1.0777

*The films are mainly chalcocite and covellite. The term 'black copper' seems to be misused.

Comparison of the foregoing figures with those from another large mine shows the following:

Leach-Liquor, Parts per Million

	Entrada	Salida
Copper	580	48
Ferrous sulphate	57,120	64,470
Ferric sulphate	3,090	2,140
Total sulphate	32,050	30,960

It will be seen that the analyses are differently reported. Calculating to ferrous iron, for comparison, we have 20,563 parts per million in one case as against 19,215 parts in another, in the entering solution. The low proportion of copper is noticeable. Moreover, at some plants they do not dare to return the spent liquor to the leach-piles, since basic iron salts are then deposited on the ore, resulting in a stoppage of the extraction of the copper. The average copper-content of all ore sent to the leach-yard at the Herrerias mine, for example, is 1.27%, with an average of 47.5% sulphur. In three years the copper is reduced to 0.18% (85.82% extraction), while the washed ore at that time will assay 49.5% sulphur. The heaps are treated six years, resulting in an extraction of more than 90% of the copper. At the Tharsis plant the average ore sent to the leach-yards carries 1.5% copper and 48% sulphur. After washing for six or seven years it contains only about 0.08% copper. If leached from three to five years the copper-content will run from 0.20 to 0.25%, and if the ore has been too fine and too compact in the pile the residual copper contained after five years of leaching may be as much as 0.50%.

Whether the differences mentioned above are due to differences in the character of the ore or to differences in the skill of manipulation is not always apparent. Perhaps both figure in the divergence observed. While there is no large mineral area in the world where greater uniformity in the character of the ore is seen, there are distinctions that the technologist discovers, as, for example, the ore from certain mines decrepitates more freely, while in others it is more 'free-burning' than that from other deposits. The San Telmo ore is especially celebrated for its free-burning quality.

In addition to the ordinary leach-liquors from the cementation yard, the mine-waters are always sent to the leach-system. Whereas the strong liquors contain above 3000 parts of copper per million the mine-waters usually contain no more than 600 parts. Pumps are no longer used at the mines, all types having proved expensive. Accordingly wooden bailers are employed, coated with tar and bound with copper. At the San Dionysio, as reported by Peña, two bailers run in balance, each having a capacity of two tons of water, and the daily capacity, during a bailing-period of 20 to 21 hours, is 300,000 gallons. The bailer makes a round trip from the surface to the 32nd level in 2½ minutes.

Considerable water also comes from the Lago pit on the north side of the ridge known as Solomon's mountain. It is interesting, in passing, to note that the Lago has been an important source of the Rio Tinto, that is, the river of that name. Accordingly this ore has been

subjected by nature to nearly the same conditions as those present in the leaching plants. This mine is so low in copper that the greater part of the ore does not pay to be handled through the cementation plant; it averages 50% plus in sulphur, and is the best pyrite for acid-making produced at the Rio Tinto. The Lago pit is 1700 ft. long, 800 ft. wide, and about 500 ft. deep.

The copper-bearing liquor going to the precipitation plant invariably has a deep emerald-green color. It flows to precipitation vats, built usually flush with the surface of the ground, having concrete walls, lined with two-inch plank. The concrete is painted with asphalt. A common size of vat is 100 m. long, by 1 m. deep, by 3 m. wide. In one plant there are 3500 linear feet of vat, which includes a series of shallow 18-in. vats, that follow the deeper ones. The vats are filled with pig-iron and scrap-iron, pig-iron being used exclusively in the vats through which the solutions first flow. Both Spanish and English pig-iron are used. The grade employed contains about 92% metallic iron, and is extremely high in graphite. As the solution of the iron progresses the graphite accumulates in a layer between the iron and the crust of leaf copper, or 'cascara'. Sometimes this layer of graphite becomes a half-inch thick. The speed of the solutions through the tanks is regulated in accordance with their copper-content; a solution with a small amount of copper requires more time for precipitation. Also, the weaker the solution the greater is the proportion of fine granular copper that is precipitated. This is high in grade, containing 80% metallic copper. The spent liquor, still containing about 20 gm. of copper per cubic metre (20 parts per million), in most cases is pumped back to the leach-yard by acid-resisting pumps.

The copper precipitate is all washed over screens having about ¼-in. perforations, the screens being 3 m. wide and 10 m. long. The leaf-copper collects on the screens, and the undersize flows to inclined washing-floors or 'planillas'. The fine cement-copper is here concentrated, giving a material that assays 90 to 92% copper, which is shipped. The tailing from the planilla, containing a large amount of graphite, goes to settling-vats. It is dug out from this vat at intervals, and, on drying, assays about 40% copper. This is mixed with enough granular copper from the low-grade solution-vats to make a 70% grade for melting. The average grade copper precipitated is usually about 70% metal. The iron consumed varies from 1.4 parts to each part of copper by weight up to 2.392:1.

This undoubtedly depends upon the proportion of ferric iron in solution, and also upon the amount of free H_2SO_4 present. It will be seen that the proportion of ferric sulphate is maintained relatively low at all the plants, which is the result of careful manipulation. The presence of too much oxygen at the time of washing a heap increases the proportion of ferric salt. The constant assertion is made by the superintendents of leaching that the critical point is proper aeration at the various stages of the operation. The importance of this control of aeration is reflected in the extremes between

a consumption of 1.4 parts of iron per part of copper by weight at one plant and the startling increase to 2.392 parts of iron at a less well regulated leach-yard.

I was unable to obtain data anywhere regarding costs, but figures given me by well-informed engineers in the city of Huelva, together with deductions from data furnished by superintendents at various plants, indicate that the cost of extraction of the copper by cementation has been approximately four cents, U. S. currency, per pound of copper recovered, and at one plant, where less than 2,000,000 tons of ore was lying in the leach-yards, the manager informed me that the cost was 0.385 peseta per kilogram, equal to 3½¢. per pound. This included the cost of mining, the building of ore-heaps, leaching, and precipitation. On the basis of 2% copper in the ore, and 90% recovery, this would give a total cost per ton of ore of \$1.26. The highest cost that my figures showed at any plant was 6¢. per pound of copper or \$2.16 per ton of ore. It may therefore be accepted that the total operating cost is repaid through the copper by leaching the ore from 3 to 3½ years, as previously stated, and the total copper recovered normally yields a profit without taking into account any returns from the pyrite. The latter is, therefore, a by-product.

No detailed mention has been made of the peculiar character of the silicious ore, which adds considerably to the economic results above outlined. The North pit, at Rio Tinto, contains a particularly large amount of this material, and it is nearly all high in copper as compared with the very basic pyritic ore. Similar material is found in many of the Huelva mines. The silicious ores represent porphyry that has been sericitized, and which contains chalcocite in proportions varying from 1½% copper to 9% and even 10%. The rock is bleached white, except where tinged gray from the sooty chalcocite, and it is friable and granular. In many places the chalcocite is found in seams from the thickness of a knife-blade up to a half-inch. Such ore is not mixed with the pyrite, but is stacked in separate heaps for leaching, the thickness of these heaps being less than when pyrite is used. The object is to permit free ventilation. The chalcocite oxidizes and leaches in the course of years, and, as a pile becomes depleted of its copper, fresh ore is piled on top. Thus the copper is recovered without other treatment. This ore is similar in appearance to the disseminated ores from the Inspiration, Miami, and Nevada Consolidated mines in the United States, and I am told that it will concentrate equally well by flotation, but that the methods of leaching pursued are more economical, even when the interest on the capital locked up for so long a period is taken into account. The time required for leaching such silicious ores is ten years.

Through these silicious orebodies are seams of some width that carry silver, sometimes as much as 50 oz. per ton, but more commonly 10 to 15 oz. This ore is kept apart, as far as possible, for separate treatment.

THE value of gold sold by the Gold Producers Association of Australia from February 1919 to October 1920 was \$31,908,889, and it is estimated that by the end of

1920 gold sold and exported reached a total of \$35,235,000. The bulk of the gold hitherto exported has been marketed in India, China, and Malaya, but a sale of gold, equal to about 164,700 oz., was recently made to American bankers at a price which will return to the Association \$4,646,160, yielding a premium of \$1,244,160.

Fire Hazards at Mines

Some of the following conditions are frequently found around a mine. All of them tend to increase the risk from fire. They are noted by B. O. Pickard, engineer for the Bureau of Mines.

Wooden head-frames.

Planked floors around the collar of the shaft or adit-portal.

Frame buildings in the immediate vicinity of the collar of the shaft or adit-portal, often grouped about the collar. At several mines frame buildings have been built over the shafts and adit-portal.

Mining timbers piled in the immediate vicinity of the collar of the shaft or adit-portal.

Cans of oil and gasoline standing at the collar of the shaft or adit-portal.

Boxes of dynamite near the collar of the shaft or adit-portal.

An accumulation of waste materials and refuse around the collar of the shaft or adit-portal.

Wooden snowsheds leading to the mine-portal with rooms in the snowsheds for blacksmith-shop.

Accumulation of oil, waste, and paper, in the inclined timber sets immediately below the collar of the shaft.

Pump-house and hoist underground not fireproofed; uncovered oil, waste, and cans of lubricating oil in the immediate vicinity of the pumps and underground hoists.

Accumulation of combustible rubbish, dynamite, and mine-timbers at underground stations.

Electrical apparatus not properly insulated and not placed in fireproof stations.

Underground magazines in unclean condition; boxes and papers permitted to accumulate; dynamite in working places.

Large carbide containers left open, partly filled with carbide.

Pulleys and idlers in shafts permitted to run dry and hot.

No attempt made to control ventilation.

No fire-extinguishers nor fire-hose on the surface or underground.

No self-contained oxygen-breathing apparatus.

No men trained in the use of the self-contained oxygen-breathing apparatus.

No systematic plans made for fighting fire.

No disaster signals.

No arrangements for converting the air-lines into water-lines to fight fires.

No fire-doors.

No fire inspection in the stopes.

No thought given to fireproofing shaft-collar, shaft-timbers, and stations.

Teaching Engineering Students to Write

By Homer A. Watt

*When the chairman of your Program Committee did me the honor to request that I read at your conference a paper on the general subject of technical writing, I replied that I was neither an engineer nor an editor, and that I did not presume, therefore, to instruct editors in the composition or revision of technical articles, but that as a college teacher of English who has struggled for several years with the task of making engineering students more articulate, I should be glad to tell of my own problems and methods. It is my purpose to point out first the extent to which editors of technical journals are concerned with the efforts of college teachers of English composition, then to outline the training methods which the English departments of technical schools are now following, and finally to suggest in what ways the editor may assist the teacher to solve the problem with which both are struggling, that of creating a higher standard of craftsmanship in technical papers.

The service of the teacher of composition in the technical school to the editor of the technical journal is that of the drill-master who trains the soldiers to the general who leads them into battle. It is our humble task as teachers to struggle with fogginess of thought and incoherencies of expression, and by pointing out his defects to the student so train him in habits of self-correction that the manuscripts which he submits to editors will be tolerably free from the errors that have helped to make us wrinkled and gray. Although I have no statistical evidence of the assertion, I believe that most of the contributors of the substantial articles to the technical journals have been trained in professional schools. Men so trained have a feeling of membership in the engineering profession; they see their own tasks in relation to the work of toiling engineers elsewhere, and so are eager to reach out and exchange experiences and opinions through the medium of the technical press. But skill in expression does not come with desire, and many of these men are handicapped by lack of experience in writing. An engineer told me only a few days ago of the comical agony of an expert in electrical meters who was called upon to present a paper on that subject before an engineering society. This master of electrical meters knew his field thoroughly, but the task of selecting and arranging and expressing his ideas for the understanding of others was quite beyond him.

Engineers who have not been trained in literary craftsmanship as students frequently remain incoherent and clumsy in expression for the rest of their lives. In the rush of their professional work they are too much pre-

occupied to study the art of writing; what little skill they do acquire they gain by practising on their associates, their correspondents, and the editors. The editors, cursed though they are by badly written contributions, cannot take the time to teach composition. The interest of the college teacher is in the process of training; that of the editor must be in the finished product. In revising for a New York editor a very badly written manuscript, I suggested that the author would improve under instruction. "That may be", was the reply, "but if his stuff is so rotten that we can't print it, we'll have to turn it down; we can't afford to give the man a course in writing—that is not our business." But this training in writing is exactly what the college teacher aims to give; our highest hope is that the engineering students whose 'themes' we have carefully corrected and criticized will not burden editors and others with the compositional abortions that we have struggled to put into shape.

"Is it possible to teach engineering students to write?" an engineer asked me the other day. Yes, it is possible, just as possible as to teach them mathematics and mechanics, provided we are satisfied with humble results and do not expect our students to acquire the literary finish of a Huxley. To be sure, some of our effort will be wasted; many of our students will never write because they will always lack ideas and incentive to expression. But some will think better and write more coherently for their training, and from them our reward will come. Among teachers of college English I have met those who profess to believe that all efforts devoted to teaching engineering students to write are wasted, but I have never agreed with these skeptics.

There seem to be at present three different systems or 'schools' for the teaching of composition to engineering students. These are alike in being based on analyses of essays and constant practice in theme writing, and in aiming primarily at correct and effective expression. They differ in material employed, in method of attack and in secondary objectives. I will define and comment briefly on each.

The first refuses to give the engineering student special consideration. In universities in which the English department is in the college of arts, the engineering student is usually put through the same mill as his brother in liberal arts under the theory that he gets too little contact with cultural subjects and needs more. Where this point of view is sincere and the attitude of the instructor is sympathetic and understanding, such a process is hardly open to adverse criticism. Unfortunately, however, too many teachers of English dislike to instruct engineering students and assume toward them an attitude of academic pharisaism to which the students are quick

*A paper read at the meeting of the National Conference of Business Paper Editors, in New York, on October 21, by the Associate Professor of English in New York University.

to respond in a cordial hatred of their work in English. I do not believe, moreover, that most engineering freshmen (the course is usually given in the freshman year) can be made to see that a purely academic course in English composition has any connection with the engineering course which they insist they have come to college to take. It may be argued that the English course is good for them, and that some day they will realize its value, but if their attitude while they are taking it is negative, not to say rebellious, it is hard to see how they can get much out of it.

The second type of course, given also usually in the first year, is especially designed for the engineering student. It aims, like the first, to give him culture and training in expression, but it has also the unique aim of refining for him the profession which he is preparing to enter and helping him to think of himself and of his technical school education in terms of his ultimate service to his fellow-men. To this end he analyzes essays which define engineering and which comment on the value of the different subjects he is studying and on such big themes as the relation of science and literature and of 'practical' work and 'chamber' work; in addition he is asked to write themes based on his reactions to this reading or drawn from his personal experiences or reflections. Three collections of essays which meet the demands of his type of course have so far been edited. They are: Aydelotte's 'English and Engineering' (McGraw-Hill, 1917), Eason and Weseen's 'English, Science, and Engineering' (Doubleday, Page & Co., 1918), and Baker's 'Engineering Education: Essays for English' (Wiley, 1919). The obvious advantages of this course are in its probable stimulation. It is the theory of Professor Aydelotte, originator of the plan that after a brisk classroom discussion of one of the essays, the members of the class will become filled with ideas and with enthusiasm for expressing them. With a sympathetic teacher, skilled in leading classroom discussions, this result may be reasonably expected; with a dull, indifferent, and indolent teacher, on the other hand, these classroom 'discussions' may easily degenerate into vapid and hypocritical comments by both teacher and students, and the prime object of all work in composition, instruction in writing, may be lost sight of.

The third type, usually given, I believe, after the first year, is frankly professional in aim. On the assumption that the great majority of engineers are likely to write more technical descriptions, explanations of processes, reports, and business letters than any other kind of composition, the students are trained in these forms. It could not be understood that the student themes are highly technical or complicated but that the student is doing the same kind of writing as is the practising engineer; his explanation of how he wired his house, and his description of the chemical laboratory differ only in degree of difficulty, not in kind, from the papers of his seniors. The advantages of this method of drill are in the interest which it arouses in the student, who is made to see at once the relation of English to engineering, and

in the direct application of his training in English to his practice. Shortly after I had introduced a course of this type in the junior and senior years of the engineering school of a large Middle-Western university, I was told by one of the engineering instructors that there was a noticeable improvement in the quality of the senior reports and theses. The disadvantages of the course arise from the difficulty of securing instructors with a sympathetic point of view and a willingness to do the work painstakingly and thoroughly, and from the danger of binding the student too narrowly to his technical interests. To avoid this latter danger I believe that the course in technical writing should follow, not supplant, the cultural course in English composition. The special texts which so far have been prepared for courses in technical writing are: Earle's 'Theory and Practice of Technical Writing' (Macmillan, 1911), Sypherd's 'Handbook of English for Engineers' (Scott, Foresman & Co., 1913), and my own 'Composition of Technical Papers' (McGraw-Hill, 1917).

I have taught English composition to engineering students under all of these systems, but since editors of technical journals are interested chiefly in technical papers, I will outline some of the aims and methods which have guided me in giving courses of the third type. It should be understood that many of these are also applicable to the other types of instruction which I have enumerated.

First let me sketch the general objectives of a course in technical writing. English is regarded frankly as a tool, and students are taught to understand its value as a tool and to think of written expression as natural and not unusual even for engineers. An effort is made in the course to bring the prospective engineers to regard the technical journals as a great unfinished but ever growing encyclopaedia of engineering knowledge, in the making of which it is at once their duty and their privilege to assist and through which they may touch elbows with other workers in their great profession. Through their theme writing they are given fundamental training in logical thinking; they are taught to make careful conservative statements, to avoid wild generalities and *post hoc*, *propter hoc* fallacies, to test the validity of their evidence and its applicability to a given conclusion, to indicate the limits of possible error and alternative solutions which should fairly be considered—in brief, to draw tighter the meshes of their thinking. They are trained further to keep constantly in mind the point of view of their readers, to remember that ideas and facts which may be perfectly clear to writers who are engineers may not be equally clear to laymen. They are frequently instructed to write an explanation or a description as it should be presented to engineers, then to city councilmen, then to farmers, and they are graded on the skill which they show in selecting their facts and adapting them to the intelligence and special interests of their particular audience.

In teaching engineering students to write themes, I have never attempted to accomplish too much; it is much

better to aim at securing clear organization and correct expression than to try to develop literary style. "All engineering students," a professor of electrical engineering once said to me, "tend to think in terms of formulas." I believe that he is in general right, and I give my students compositional instructions that are definite and understandable even if not always easy to apply immediately. Some of these are: (1) Begin every paper with a clear statement of your subject. (2) Have a logical plan clearly in mind, and announce the new divisions of your paper as you come to them. (3) Proceed usually from general statements to details—not conversely. (4) Explain things which your reader does not know in terms of things which he does know. (5) Write fairly short paragraphs—not over two hundred words—each devoted to a definite phase of your subject that is stated clearly at the beginning of the paragraph. (6) Make sure that every sentence is as clear to your room-mate as it is to you.

The elements of the course are classroom talks on writing, and classroom criticisms, *pro* and *con*, of student themes and published articles on technical subjects, papers, which are corrected and criticized by the instructor and returned to the student for his correction, and frequent personal conferences in which the peculiar besetting compositional sins of the student are hammered persistently and relentlessly. All of this work is accompanied by a continual drum-fire drive against bad thinking and bad structure, and against illogical statement, rambling sentences, weak reference of pronouns, misplaced sentence parts, and all the thousand and one devils of bad craftsmanship that wear out the blue pencils of worried editors. At the end of such a course if the student does not have the style of Huxley, he can usually, at least, write more correctly and more clearly, and is better prepared to share creditably in the making of a technical journal.

By announcing at the beginning of this paper that I should conclude with some suggestions as to how editors of technical journals might help college teachers of English to train engineering students to write, I did not mean to imply that editors have not already done much in this direction. Concern with the finished product has certainly not kept some editors from doing what they could to help make better writers. I have in mind such activities as those of Mr. G. A. Wardlaw, whose address on 'Literary Engineering' appeared in the 'Sibley Journal' several years ago, of Mr. G. M. Wood, author of an excellent manual for the guidance of members of the U. S. Geological Survey, and of Mr. T. A. Rickard, whose accurate and scholarly 'Technical Writing' (Wiley, 1919) sets a high standard for all contributors to technical journals. By continued insistence upon clear and correct and carefully prepared manuscripts, and even, I believe, by occasional 'lessons' in composition in the pages of the journals—simple hints to authors similar, perhaps, to those published in pamphlet form by the A. I. E. E.—the editors can keep up among engineering contributors an interest in high standards of literary work. And by

pressure brought to bear upon the administrations of technical schools and colleges to give more work and better work in English, and by closer associations with teachers of English composition in these schools, editors may assist greatly in the training of students. Teachers of English composition in engineering schools will welcome such sympathy and assistance, for after all editors and teachers have the same aim—that of eliminating error and of gradually improving literary craftsmanship in the engineering profession.

Ore-Testing at Golden, Colorado

The current bulletin of the Colorado School of Mines explains three arrangements under which its metallurgical testing plant may be used by the public.

(A) Any responsible person or organization may, with the consent of the director, use the equipment by paying for the actual material, labor, power, water, expert assistance used, and depreciation. In this case the person using the plant is responsible for the accuracy of the results obtained.

(B) The director of the plant and his assistants will conduct a test, in which case a charge equal to the cost of similar work done by a commercial testing plant or by a consulting engineer will be made. If desired, the director will make an estimate of the cost previous to starting the work, but this will not be used in billing the actual charges. The director will be responsible for the accuracy of the results, and will make a report to the person authorizing the test without stating that the ore comes from any particular mine or locality, unless he supervises the arrangements for taking the samples. The director will not suggest suitable devices nor recommend machines put out by various manufacturers for the commercial plant that will subsequently be built as a result of his test-work. The person receiving the report of the test-work should employ a consulting engineer to advise further in regard to the building of a commercial treatment plant.

(C) A person or organization desiring to conduct a prolonged research may establish a fellowship at the school under the director, to cover a period of one year or longer, and the fellow may give all or part of his time to the special research work. In the latter case, the greater part of his time will be devoted to the special research and the remainder to post-graduate study. The person establishing the fellowship will pay the salary of the fellow and the actual cost of material, labor, power, water, and depreciation necessary for the research work. The director and his staff will supervise the work of the fellow without charge, will assume the responsibility for the accuracy of the results obtained, and will make a complete report of the work performed. This will not be published for a period of two years without the consent of the person establishing the fellowship. Any patents to cover any part or all of a process developed by the fellow under this agreement will be assigned to the person establishing the fellowship.

The Fairhaven Silver-Lead District, Alaska

By Lewis A. Levensaler

INTRODUCTION. The mining area to be described is on the north drainage of the Seward Peninsula, in latitude $5^{\circ} 40'$ North, longitude $162^{\circ} 30'$ West, at an elevation of approximately 500 ft. above sea-level.

The district is reached from Seattle by steamers of the Alaska Steamship Co., by way of Nome to Kiwaulik, on Kotzebue Sound, or by launches from Nome to Kiwaulik, 50 miles, thence to Candle by small river-boat, from which point wagons can be used or sleds in the winter, a distance of 28 miles to the camps.

Candle is a town of about 100 population at the junction of Candle creek and the Kiwaulik river. The town has a good general store, two hotels, a post-office, and tele-

Native coal as fuel can be used for a limited amount of power during development, but eventually other arrangements would have to be made. The native coal is an inferior grade of lignite. The veins dip at a steep angle and are badly crushed and broken. Neither the quality of the coal nor its physical condition offers much encouragement for development. There is one hydro-electric possibility in the district that can be utilized for six months in the year.

TOPOGRAPHY. Practically the entire northern half of Seward Peninsula is characterized by broad rounded hilltops and wide shallow valleys. Everywhere there is evidence of long and continued erosion suggesting great age. The surface is covered with tundra and coarse bunch-grass forming what is known as 'nigger-heads'. The area is practically treeless, although a very limited amount of scrub spruce grows on the tributaries of Independence creek. In the summer the district is well supplied with water and small streams, none of which are navigable.

GEOLOGY. The mineral zone that harbors these silver-lead deposits has been traced a distance of about a mile. The general strike is north and south with a fairly steep westerly dip. The exposed rocks are mostly schist, limestone, and granite. With the excep-

THE INDEPENDENCE MINE, AT THE JUNCTION OF INDEPENDENCE CREEK AND THE KUGRUCK RIVER, IN ALASKA

none connection with Nome, which is served by both wireless and cable from Seattle.

Navigation in Bering Sea opens early in June and closes early in November. During these five months the Alaska Steamship Co. makes four trips to Nome and one trip to Kotzebue Sound. Therefore, all freight to and from the district is dependent on one steamer per annum. Freight-rates from Seattle to Kiwaulik (ship's tackle) average, \$15 per ton, lighterage \$7, on river boat \$3, plus \$10 per ton from Candle, or \$85 per ton to the camps. Winter freight can be contracted in quantity from Candle to the camps for \$20 per ton. The cost of feeding men averages \$3 per day per man. All labor is paid \$5 per day and found. The quantity is scarce and the quality poor. With reference to hard-rock miners, there is practically none of this class of labor in the country. Miners would have to be imported until a number of properties are operating. Except for boat-work and packing, Eskimo labor is worthless.

tion of an occasional granitic stock, there is an absence of igneous rocks. The older formations, largely made up of sedimentaries, have been so altered and sheared by severe dynamic metamorphism that it is impossible to identify the rock from which the present schist is derived.

The schist and limestone strata are highly inclined, and it is along their faulted contacts that the mineralization has taken place.

The ore is made up of argentiferous galena, zinc-blende, gray copper, and a small amount of pyrite.

The veins or contact shear-zones are filled with fault material containing bodies of siderite replacing limestone to a variable extent. Galena and zinc-blende, the principal ore-minerals, are later than the siderite and occur as a replacement of both the limestone and the siderite. This sequence has an important economic bearing on the deposits.

The well-crystallized character of the minerals sug-

gests that the deposits are later than the deformation of the region, that is, the mineralization took place after the limestone and calcareous schist were inclined to their present position. Cross-slips, existing prior to the mineralization, undoubtedly control the forming of the ore, as reflected in the assays of samples on the foot-wall side of the faults. Along these slips much movement and subsequent faulting has taken place.

The principal development in the district consists of a shaft 140 ft. deep from which two levels have been run. This shaft was sunk on an outcrop of good lead ore, a sample 18 ft. down the shaft returning 30.5% lead and 27.8 oz. silver per ton, across a width of five feet. A drift has been started at the 40-ft. level following the schist-limestone contact. The limestone on the hanging wall has suffered the greatest deformation, the schist on the foot-wall being more defined. This level has disclosed four separate faulted orebodies:

No. 1 averages 10 ft. wide by 75 ft. long with a value of 6.8% lead and 6.1 oz. silver per ton.

No. 2 is 38 ft. across at the widest point and possibly 20 ft. long, assaying 7% lead and 10 oz. silver per ton.

No. 3 averages 7 ft. wide for a length of 75 ft. with 6% lead and 6.4 oz. silver. A composite of the samples from this body returned 8.6% zinc. This percentage and ratio of zinc undoubtedly will be found to exist in all the ore in the mine.

No. 4 averages 10 ft. wide for 25 ft. in length and assays 6% lead and 5.3 oz. silver. The face of this orebody, which is the extreme south breast of the 40-ft. level, is stronger and better defined than other exposures in the mine; in fact, the workings seem to be getting into a less broken country to the south.

The irregular dimensions of the above described orebodies are due to faulting. On the 140-ft. level only one orebody has been defined; this will average 5 ft. wide for a length of 35 ft. and contains 3.4% lead and 2.5 oz. silver per ton. The south face is just entering a well-defined mass of siderite showing occasional bunches of good lead ore.

A picked sample of clean galena from boulders of 'drag' in the fault returned 61.6% lead and 40.4 oz. silver. A picked sample of clean galena, occurring largely as a replacement of limestone, returned 52.4% lead and 46.8 oz. silver. A picked sample of clean galena, occurring largely as a replacement of siderite, returned 61% lead and 54.1 oz. silver per ton. These samples were carefully selected for the purpose of determining the grade of galena and the ratio of silver to lead.

The importance of the district depends on favorable results from further development with depth or at some point along the vein; particularly if this development demonstrates that the replacement of siderite by galena is found to be more complete than at any point where it is now exposed.

The ground is soft and heavy and is held together by frost. Underground temperatures range from 28° to 30°F., to a depth of 140 ft. When connections are made for ventilation this frost will probably leave the ground

during the summer. In this event mining will necessitate the use of timber, of which there is a great scarcity in the district.

Lead Mining in Western Australia

There has been a revival of mining in the Ajana district in Western Australia according to the 'Chemical Engineering and Mining Review'.

Lead mining has been carried on in the vicinity for nearly half a century. In the early days several mines were worked by convict labor, and the ruins of the old cells and exercising yards, which were built of solid stone, can still be seen at Geraldine, the principal town. The lead was smelted at a central smelting works, about three miles south of Geraldine. The old stack is still standing on the top of a small hill, and can be seen miles away from all directions. The lead was then carted about forty miles to Port Gregory, and loaded as ballast on sailing vessels going to England.

The principal mine at work in this field is the Surprise. This mine was not worked in the early days, but has produced during the past twelve months 3000 tons of lead concentrate containing 70% lead. The lode is from 15 to 20 ft. wide, and in places 8 to 12 ft. of solid galena has been worked, it being only necessary to break the ore, raise it to the surface, and bag it. The Surprise mine has only been worked for 100 ft. vertically and for a distance of 180 ft. along the lode, but the whole of the machinery, working expenses, and development work have been paid for from profits. The clean ore is bagged, and the other lode material is sluiced; in this way an output of over 100 tons of lead concentrate per week has been maintained. The sluice tailing contains about 15% lead, and will be treated again. A mill has just been completed, consisting of a rock-breaker, three sets of rolls, four trommels, four jigs, and three Wilfley tables driven by two suction gas-engines with an aggregate capacity of 95 horse-power.

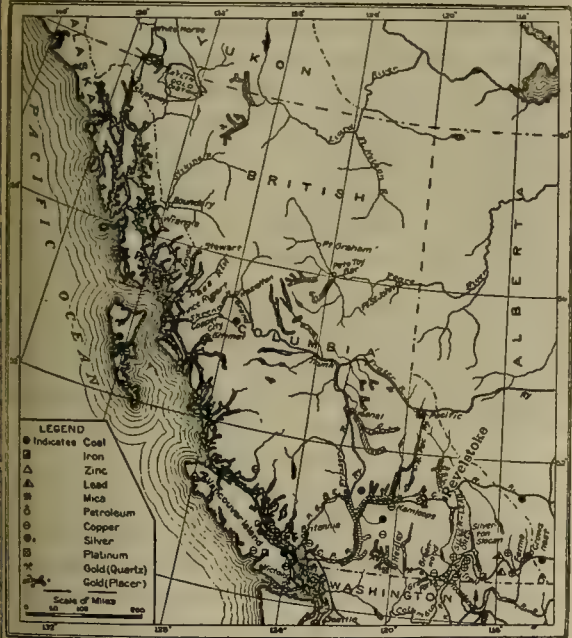

AUTOMOBILE statistics for 1920 given by Alfred Reeves, general manager for National Automobile Chamber of Commerce, follow: Automobiles registered in the United States, approximately, 8,500,000, of which 7,600,000 were passenger cars and 900,000 trucks; cars and trucks owned by farmers, 2,500,000; special taxes paid annually by the industry to the Government, \$257,000,000; registration fees, \$81,000,000; amount paid by the industry to railroads for freight shipments, \$100,000,000; cars and trucks produced, 2,241,000, of which 1,906,000 were passenger cars and 335,000 motor-trucks; wholesale value of cars and trucks produced, \$2,136,183,676; wholesale value of passenger cars, \$1,703,437,213 and of trucks \$432,746,463; average wholesale price of passenger cars produced, \$897, and of trucks, \$1273; value of motor vehicles and parts exported, including engines and tires \$338,000,000; number of passenger cars exported, 153,000; value of passenger cars exported, \$155,000,000; number of motor-trucks exported, 27,000; value of motor trucks exported, \$45,000,000.

Canadian Mining in 1920

The year 1920 was a good one for the Canadian mining industry; the estimated value of the mineral production for the year is \$200,000,000 compared with \$176,686,000 in 1919 and \$211,301,897 in 1918, the comparative figures being as follows:

	1920	1919	1918
Total mineral production of Canada, value	\$200,000,000	\$176,686,390	\$211,301,897
Pig-iron, tons	1,080,000	917,791	1,195,551
Steel ingots and castings, tons	1,220,000	1,030,342	1,873,708
Copper, lb.	82,500,000	75,053,581	118,769,434
Zinc, lb.	42,000,000	32,194,707	35,083,175
Gold, value	18,000,000	15,850,423	14,463,689
Silver, oz.	13,500,000	16,020,657	21,383,979
Lead, lb.	35,500,000	43,827,899	51,398,002
Coal, tons	16,000,000	13,681,218	14,997,926
Nickel, lb.	61,500,000	44,544,883	92,507,293

One of the notable features of the year was the marked recovery in the production of copper, zinc, and nickel, and of coal. There was also a small increase in gold production. In respect of zinc, coal, and asbestos the highest production in the history of Canada was recorded,

BRITISH COLUMBIA

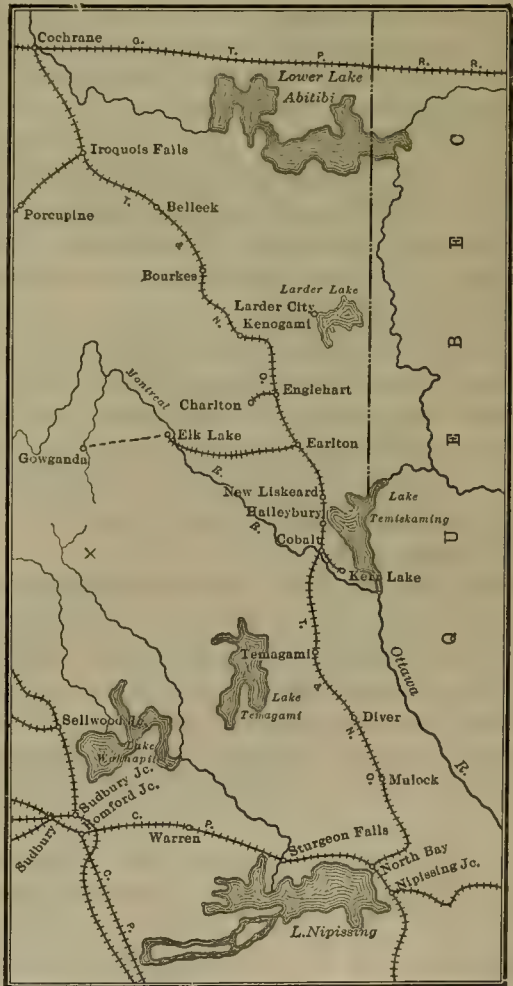

while the production of chromite, gypsum, fluorspar, mica, and salt was well sustained. The decline in prices which made itself felt during the last three months of the year naturally had a depressing effect on production and some plants will probably remain wholly, or partly, closed until market conditions improve, or until a new level of cost makes operations more profitable.

Under the stimulus imparted by the War, Canada's mineral production increased from a total value of \$128,63,000 in 1914 to a value of \$211,300,000 in 1918. The reaction in 1919 resulted in a falling off to \$176,686,000,

practically the same value as was placed upon the 1916 production. As already stated the value of the 1920 production is put at \$200,000,000, a production exceeded only by that of the maximum year 1918.

During the past seven years value of the annual production has been:

	Metallic	Non-metallic	Total
1914	\$59,380,619	\$69,476,456	\$128,863,075
1915	75,814,841	61,294,330	137,109,171
1916	106,319,365	70,882,109	177,201,534
1917	108,455,147	83,191,674	189,646,821
1918	114,549,152	96,752,745	211,301,897
1919	73,262,793	103,423,507	176,686,390
1920	80,000,000	120,000,000	200,000,000

ONTARIO

The total production of nickel is estimated at 1,500,000 lb., an increase of 38% over the 1919 production and an output that has been exceeded only during the four war years, 1915 to 1918, inclusive. The annual production of this metal in Canada for some years to come will be limited only by the demands of the market. Canada has long

been the principal source of supply for the world's markets. The developed deposits assure an ore-supply for many years, and smelting capacity has been provided considerably in excess of the highest production reached during the War. The completion by the British American Nickel Corporation of the smelter at Nickelton and the refinery at Deschenes, Quebec, the former having been placed in operation about January 18 and the latter in April, has contributed materially to the increased output during the year.

The production of copper is estimated at 82,500,000 lb., which, compared with a production of 75,000,000 lb. in 1919, shows an increase of 10%. The highest previous production was 118,769,000 lb. in 1918. The production from Quebec in 1920 was less than half that of 1919, the Eastis mine and mill having been idle throughout the year. In Ontario the production was increased about 25%. The shipments from Mandy mine in Manitoba were about the same as during the previous year. In British Columbia a slightly increased production seems to have been derived from the mines on the Coast.

The value of the gold production is estimated at \$16,000,000 as compared with \$15,850,423 in 1919. While the total value has increased during the past two years, the production is still less than that obtained in 1916, when the total was over \$19,000,000, or in 1900, when nearly \$28,000,000 was obtained.

Ontario probably contributed about 72% of the total gold production of Canada in 1920. This being derived from seven mines in the Porcupine district, three at Kirkland Lake, and several miscellaneous properties. The Yukon production, which has been steadily declining, shows a further decrease of about 30%. British Columbia's production is also believed to have declined about 20% though estimates for this Province at this time are based largely on conjecture.

Nova Scotia, Quebec, and Manitoba are at present but minor contributors to the country's gold production. Nova Scotia for many years boasted an annual production exceeding \$500,000, but in 1920 less than \$15,000 is reported to have been obtained. Some spectacular gold finds have been made in Manitoba, but the copper ore of the Mandy mine, up to the present, has been the principal source of gold. The development of the Flin-Flon may in a few years provide quite an important source of gold as a by-product.

The silver production for the year is put at 13,500,000 oz. or 2,500,000 below that of 1919. There appears to have been a general decrease from all sources. The Ontario production is estimated at about 10,500,000 oz., the falling off being due in part to shortage of power. The rapid decline in the price of silver beginning in January also tended to diminish output, particularly toward the end of the year. Silver from British Columbia has been mainly a by-product recovered from the treatment of lead, copper, and gold ores. The opening of high-grade silver ores, such as those found in the Dolly Varden mine at Alice Arm, gives promise of greater production. Those of the Mayo district, Yukon Territory, are also attracting

considerable attention, high-grade ores having been found in this district.

The production of lead is estimated at 35,500,000 lb., or 8,827,000 less than in 1919. While British Columbia is the principal source of lead and zinc, these metals have also been obtained in important quantities in Ontario and Quebec. During 1920 there was a considerable falling off in the quantities of lead ores exported to the United States from British Columbia. Shipments from Quebec were about one-third those of the previous year, while Ontario's contribution has probably been increased by over 50%. The total production during the year is roughly estimated at 35,500,000 pounds.

The estimated production of refined zinc is placed at 42,000,000 lb. There was a distinct falling off in exports of zinc ore to smelters in the United States. The price was well maintained during the first nine months of the year, though with other metals it fell off at the end of the year.

The production of coal for the year is estimated to have been at least 16,000,000 tons, which is 2,500,000 tons or 18% over that for 1919. Alberta led the provinces with an estimated production of 6,700,000 tons, the estimated value of Canada's total production being \$70,000,000.

Iron-ore production fell away considerably during the year, it being estimated that shipments from the mines did not exceed 120,000 tons. These were mainly from the mines of the Algoma Steel Corporation at Magpie mine and Moose Mountain, Ltd., at Sellwood, Ontario. The shipments from both mines consist of a beneficiated product, roasted siderite, from the Magpie, and briquettes, from concentrated magnetites, at Moose Mountain.

The total production of pig-iron from blast-furnaces and electric furnaces in 1920 is estimated at 1,080,000 tons, and the total production of steel ingots and steel castings at 1,220,000 tons, both records showing a substantial increase over those of the previous year.

THREE MATERIALS for preserving timber for use in mines have been found suitable. These are coal-tar creosote, zinc chloride, and sodium fluoride. Creosote is the most effective in preventing decay. Timbers thoroughly impregnated with it are likely to resist decay until they are crushed or worn out. Occasional objection is made to the possible fire hazard of creosoted wood, but long experience indicates that the additional fire risk is small. Zinc chloride and sodium fluoride are odorless, and if anything they tend to reduce the inflammability of wood. They are cheaper than creosote and although they do not give such permanent protection they greatly increase the life of timbers. Coal-tar creosote may be applied by the brush, dipping, open-tank, or pressure methods. Zinc chloride and sodium fluoride may be injected by the steeping, open-tank, or pressure methods. The cost and effectiveness of the methods of treatment increase in the order given. The saving possible with any of them is so great that it will pay most mines to adopt the use of some preservative on permanently placed timbers.

Karl Eilers v. Guggenheims

Mr. Simon Guggenheim's letter to the stockholders, in reply to Mr. Eilers' allegations was as follows:

To the stockholders of the American Smelting and Refining Company and American Smelters Securities Company.

Many stockholders have requested more information concerning the suit recently brought against the Company by Mr. Karl Eilers than was obtainable from the press reports. It has accordingly been deemed desirable to print the proceedings and send a copy to every stockholder.

Attached you will find:

- (1) Mr. Eilers' petition;
- (2) Answering affidavits of Mr. Newhouse and Mr. Crockett.

The memorandum decision of the court is brief and I quote it in full:

"SUPREME COURT—SPECIAL TERM, PART I

By Mr. Justice Burr.

Eilers v. American Smelting & Refining Co. and ano.—The sole question involved here is whether the petitioner, stockholder of the company, is unlawfully prevented from examining the stock book, contrary to the provisions of section 33 of the Corporation Law. In view of the sworn statement of the transfer agent of the company, that, acting under instructions from the company leave has been granted to petitioner to inspect and make extracts from the books of the company and that the representatives of petitioner have been and still are engaged in inspecting the stock books and making extracts therefrom, which fact was admitted and conceded by petitioner upon the argument, and it appearing from the papers submitted and the correspondence between the parties that the company has been at all times ready and willing to permit such inspection under reasonable conditions, the motion for a writ of mandamus is denied with costs. Submit order."

Mr. Eilers in his petition, besides alleging a refusal by the company to permit an examination of its books, made various charges of misconduct or mismanagement on the part of the directors. These charges he could not be called upon to prove on the motion heard; they could be met only by denial and answer setting forth the facts; that they received wide publicity in the public press, to the necessary injury of the company. In view of the total absence of any legitimate ground for the action, stockholders are asked to judge for themselves whether the petition was filed in good faith. Counsel for the company (Mr. John B. Stanchfield, of Stanchfield & Levy) stated in open court:

"We challenge, upon the threshold, the good faith of this application. We say * * * * * that the whole proceeding is an imposition upon the Court; the petitioner has been neither fair nor candid in his treatment

of the Court, and the whole object that he seeks to attain is to use a judicial proceeding in a campaign for votes so as to escape the consequence of libelous accusations."

I emphatically deny, both on my own behalf and that of my brothers, all charges of improper conduct made by Mr. Eilers in the following pages, and assert that at all times my brothers and myself have sought honestly and faithfully, to the best of our ability, to further the interests and the welfare of the American Smelting and Refining Company.

Our connection with the company's affairs began in 1901, and it is with pardonable pride that we point to the development of the company in the intervening period, as shown by the following comparison:

	1902	1919
Quick Assets	\$18,000,000	\$54,486,000
Profit & Loss Surplus..	2,900,000	25,974,000
Annual turnover	82,000,000	243,000,000

That the policy of the present management has been successful is evident from the fact that in the fiscal year of the company ending April 30, 1901, the net earnings of the company were \$3,828,000, representing 3.83% of the then outstanding capital stock; during the six and two-thirds years ending December 31, 1911, the average annual net earnings were at the rate of \$12,145,000, or at the rate of 8.15% of the then outstanding capital stock; during the three years ending December 31, 1914, the average annual net earnings of the company were at the rate of \$12,165,000, or 8.28% of the then outstanding capital stock; during the three years ending December 31, 1917 (these being war years), the average annual net earnings of the company were \$21,375,218, or at the rate of 15.19% of the then outstanding capital stock; in the year ending December 31, 1918, the net earnings were \$13,887,000, being 11.10% of the then outstanding capital stock; during the year ending December 31, 1919, the net earnings were \$11,248,000, being 9.09% of the then outstanding capital stock, the latter year being a reconstruction year following the signing of the Armistice, during which industrial and commercial conditions were generally unsettled. (All figures for net earnings are without allowing charges for depreciation, as the company's records, prior to 1911, were kept on that basis.)

While my brothers, because of advancing years, have been compelled to restrict somewhat their business activities, so long as any of us are connected with the company, we shall continue, as in the past, to work faithfully and unselfishly for the company's best interests, and to exercise our best business judgment in the management of its affairs.

It is regrettable that a sensational and wholly unnecessary suit should have been brought in a period of drastic readjustment of all security values, inevitably causing a needlessly severe and unjustifiable fall in the market price of the stock of the company.

Respectfully,
SIMON GUGGENHEIM,
President.

Dec. 30, 1920.

Metal Production in Nevada in 1920

The gold output of Nevada decreased from \$4,541,502 in 1919 to about \$3,579,000 in 1920, a decrease of more than 21%. The Goldfield Consolidated property, for several years the largest gold producer in Nevada, was operated by the Goldfield Development Co. for a short time, and a comparatively small production was reported. The output of gold from the Tonopah district, however, increased from \$771,804 in 1919, to about \$1,063,000 in 1920, on account of the larger output of the accompanying silver, which was favored by a high price. The Nevada Consolidated company, at Ely, operating the largest copper mine of Nevada, was also the largest producer of gold in the State. The Elko mine, at Jarbridge, was the largest producer of gold from gold ores, and the Tonopah Belmont company produced the most gold from silver ores. Other companies that made an output of gold valued at more than \$150,000 each were the West End, Tonopah Extension, Consolidated Virginia, and Tonopah Mining. The Fairview Round Mountain, Round Mountain, Rochester Mines, Elko Prince, Montana-Tonopah, and Florence companies were also producers of gold, though several of these failed to reach the output of the previous year. The mines of the Comstock district were active, especially in development work, though their output of gold was somewhat less than in 1919, when they produced \$355,640. In the Rochester district, the Rochester Mines Co. was a large producer of gold, and there was a fair increase over the output of 1919. Late in the year the new dredge of the Gold Canyon Dredging Co. began operations near Dayton.

The mine production of silver increased in quantity from 6,863,580 oz. in 1919, to about 7,786,000 oz. in 1920, and in value from \$7,687,210 to about \$8,480,000. The large mines of the Tonopah district produced about 4,970,000 oz. of silver in 1920, against 3,568,875 oz. in 1919, and 5,299,920 oz. in 1918. The largest producers of silver were the Tonopah Belmont, West End, Tonopah Extension, Tonopah Mining, and Montana-Tonopah companies. Large quantities of silver were also produced by the Rochester Mines, Tonopah Divide, Spruce Monarch, Black Metals, Consolidated Virginia, Prince Consolidated, and Nevada Packard companies. The Comstock district produced about 268,000 oz. and several properties at Rochester produced about 572,000 oz. In Churchill county a decided decrease resulted from the idleness of the Nevada Wonder mine.

The output of copper increased in quantity from 52,331,175 lb. in 1919 to about 55,790,000 lb. in 1920, but decreased in value from \$9,733,599 to about \$9,551,000. The output was less than half of that of 1918. The Nevada Consolidated at Ely, in White Pine county, was the largest producer and contributed more than 4,000,000 lb. of copper per month; but the Consolidated Copper Mines in the same county made no effort to produce copper under the prevailing conditions. The Mason Valley smelter at Thompson, in Lyon county, was idle during the entire

year, and many of the mines of Lyon and Mineral counties therefore found it impossible to operate.

The mine output of lead increased in quantity from 15,349,370 lb. in 1919 to about 19,510,000 lb. in 1920, and in value from \$813,517 to about \$1,592,000. The Prince Consolidated mine at Pioche and the Yellow Pine mine in Clark county were large producers and there was a greater production from the Virginia-Louise, Black Metals, Bristol Silver, and Combined Metals near Pioche. Other large producers were the Spruce Monarch in Elko county and the Louisiana Consolidated in Nye county, where a new lead smelter was operated for a short time.

MAP OF NEVADA

Near Arden in Clark county a body of lead ore was opened in the Potosi mine, formerly a large producer of zinc.

The output of recoverable zinc increased slightly in quantity from 9,004,698 lb. in 1919, to about 9,100,000 lb. in 1920, and in value from \$657,343 to about \$737,000. In 1920, as in past years, most of the output was made in the Yellow Pine district in Clark county, where the Yellow Pine mine is the largest producer. The Consolidated Copper Mines in White Pine county made large shipments of zinc ore, but the output was only about half that of 1919. The average price of zinc for the year was more than eight cents per pound, but in November and December the price dropped and the Yellow Pine mine was closed.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

FURTHER CURTAILMENT AT SACRAMENTO HILL.

BISBEE.—A further reduction of steam-shovel and stripping operations on Sacramento hill, to go into effect on February 1, has been announced by the Copper Queen branch of the Phelps Dodge Corporation. Operations on the hill were greatly reduced on the first of the year, and this reduction will leave but a small part of the normal force at work. The reduction, it is announced, is due to the present condition of the copper market and to delay in completing the 4000-ton concentrator that is being erected to handle the ore.

MIAMI.—Lateral development is being carried on by the Van Dyke Copper Co. on the 1550-ft. level to explore the zone of mineralization entered in the shaft at this depth. The present work is expected also to cut the orebody that was struck in the shaft between the 1183 and 218-ft. levels, as the orebody dips in that direction. Preparations for sinking the shaft on the Louis d'Or property are progressing. The site for the shaft has been cleared and a good road built from the main Lost Gulch highway to the site. Work is held up temporarily pending the arrival of a new hoist and large horse-power boiler from Los Angeles. Five carloads of timber and other supplies have arrived at the site.

GLOBE.—The accident record of the Old Dominion Copper Co. for the past year shows a decided improvement, according to a report issued by W. G. McBride, general manager. The record is credited to the work of the men in the first-aid and safety classes. The following departments have made a perfect safety record for the year, having no lost time due to accidents in the entire year: electric shop, carpenter shop, and railroad. The following departments show a decided improvement over last year: mine department, underground; mine department, surface; crusher and sample-mill, miscellaneous surface. The mine department's underground record was marred by one fatal accident.

PRESCOTT.—Sinking operations with a force of about 20 men is about to be started at the property of the Kay Copper Co. at Canyon. The company has diamond-drilled the property and sunk a shaft 200 ft. New electric equipment has just been installed for further sinking operations.

KINGMAN.—It is announced by S. D. Stewart that the litigation involving the Schuylkill mine at Chloride has been settled. In the terms of the settlement the Garbutt

interests transfer to Richard H. Cole their holdings in the Schuylkill company as well as all claims against the property. Full payment to clear the property is to be made by instalments at regular intervals until February 1922 when the last payment is to be made. To bind the transaction \$40,000 has already been paid to Mr. Garbutt. A new corporation with a capitalization of \$10,000,000 is to be formed. Money to meet the payments and carry on active development at the mine is assured.

COLORADO

DREDGING OPERATIONS NEAR BRECKENRIDGE AND KOKOMO.

BRECKENRIDGE.—The Blue River Placer Mining Co. has been incorporated to take over and operate the dredge on the Lambing placer formerly controlled by the Blue River Dredging Co., whose interest is absorbed. The dredge is operating in the main stream of the Blue river where ample water is available for dredging.

CRIPPLE CREEK.—Properties resuming operations since the first of the year include the Blue Flag, Dante, Gold Sovereign, Pharmacist, and Findley, the last two are under long lease to the Le Brun company of New York. Heavy production is being made from the Cresson mine, the present week's shipments exceeding 1750 tons. Ore is moving forward to the Golden Cycle mill at the rate of eight to ten standard cars daily.

KOKOMO.—The Silver Queen mine in the Consolidated Ten Mile mining district of Summit county, owned by the Mutual Co-operative Mining Co., has been leased for a five-year term to the Kokomo-Recen Development & Dredging Co. and equipment is now being installed. The Terry process of flotation, tested successfully on Kokomo ores, is now being installed in the Wilfley mill. The district will benefit when the plant is ready to handle custom ore.

Machinery has been shipped to Kokomo by the National Mining & Development Co. for installation on the Golden Queen adjoining the Queen of the West, a former rich producer of high-grade silver ore. The company has tested its placer ground in McNulty gulch, the results indicating a maximum gold content of \$4.10 and a minimum of \$1.05 per yard. A dredge has been purchased and will be erected in the spring.

GEORGETOWN.—Development of virgin territory traversed by known lodes of Columbia mountain has been started by a cross-cut from the main tunnel of the Georgetown Tunnel & Transportation Co. The first of

these veins should be cut at 175 feet. The main adit is being extended into Democrat mountain. Local lease operators have secured blocks of the Waldorf-Imperial and preparations made for development. Denver men are reported to be financing operations. The working force at the Scepter property has been increased and production will be increased. A flotation unit is to be installed at the Burleigh mill at Silver Plume. The plant is being remodeled.

LAKE CITY.—Encouragement has been given operators by returns on a carload shipment from the Hiwassee mine. Settlement sheets show a lower treatment-charge made by the smelter, and payment is made for 3.2% lead. The ore shipped averaged \$100 per ton. This is the first time on record the smelter has paid for the lead content of Lake City ore. The Ute and Gladiator mines, old-time producers, are active under lease after long idleness and are again producing and shipping.

The Excelsior-Broker group of Capitol City is again producing under management of W. E. Mendenhall. The Capitol, Broker-Excelsior, and Yellow Medicine may be consolidated under the same management. A modern mill will be constructed if the merger is consummated.

TELLURIDE.—The Shoofly tunnel on the Carbonero group at Ophir is to be extended by the Rutilla-Brown Leasing Co. While this work is in progress production will be maintained from the cross-vein now producing between 85 and 100 tons daily. During 1920 a large tonnage of milling ore was developed and several cars of high-grade ore netting \$2000 per ton were shipped by the leasing company. New machinery at the San Bernardino mill has been started with satisfactory results.

MICHIGAN

REVERBERATORY FURNACE AT QUINCY SMELTER COMPLETED.

CALUMET.—Calumet & Hecla has completed a shipment of 320,000 lb. of copper to France. This is the first good-sized order received in some weeks and it is considered an encouraging indication. Domestic business has become negligible and it is estimated that the shipments from all of the lake mines in January for Eastern points have not aggregated 200,000 lb. The Stanton mines—Mohawk and Wolverine—have not been selling metal for at least 30 days and none of the other Lake Superior mines is disposed to release its surplus until the market improves. Most of the copper piled up on the docks represents from 15 to 20c. per pound in cost and there is no incentive to dispose of the metal at current prices. Present production is costing less, but the average is not better than 14c. While the reduction in wages has had something to do with the decreased cost, the principal factor is the improvement in efficiency in all of the mines.

The new reverberatory-furnace plant at the Quincy smelting works at Ripley has been completed. It makes the Quincy smelter one of the most modern and complete in the district and will add greatly to its efficiency and capacity. The building, which is of steel, houses a

22-ft. Walker casting-machine, arranged to turn out general shapes or anodes. The furnace is 16 by 32 ft., with a 300-hp. boiler in a by-pass stack of 100 ft. The furnace will refine 130,000 lb. at a charge, compared with the previous maximum of 55,000 lb. The plant is equipped with a 12½-ton 3-motor crane to charge the furnace and a 6-ton 4-motor crane to serve the casting-room, also a 2½-ton capacity slag-pot operated by a combination battery and trolley locomotive. The refined copper will be handled by an electric truck.

The New Baltic shaft of the Arcadian Consolidated is now bottomed at 800 ft. Sinking will continue to a depth of 942 ft., which corresponds with the 900-ft. level of the New Arcadian shaft, at which points the two shafts will be connected. The New Baltic shaft will reach its objective about March 1, it is expected. No drifting or stoping will be attempted until this preliminary work is accomplished. The New Baltic shaft is in the lode for the greater part of the time and the showing is declared to be encouraging.

NEVADA

REVIEW OF PRESENT OPERATIONS AT GOLDFIELD.

GOLDFIELD.—At 1440 ft. from the main south drift, the south-east cross-cut on the seventh level of the Florence is thought to be close to the vein, as the formation is harder and seams of quartz are showing. This cross-cut is timbered for the entire length with 10-in. round Oregon-pine timbers. Mellan and Howard, lessees working on the 152-ft. level of the Gem block, north-east of the Florence shaft, have shipped a carload of ore assaying \$155 to \$160 per ton, according to the final sampling at the mine. The ore-shoot has been exhausted above the level, but it has been followed for 20 ft. in a winze and other shipments will be made. The Smith lease on the Daisy block has shipped to Selby one-quarter ton of rich ore saved in following a narrow seam. Barker, Heiden, and Witt, leasing near the stope of the old Engineers' lease, have saved nearly a carload of good ore at a depth of 209 ft. Four headings are being driven in the Cracker Jack lease in the vicinity of the Little Florence shaft and two cross-cuts are being driven from the Red Hill shaft into the block leased by that company from the Florence. In all 14 headings are being driven by lessees. The first shipments from the Consolidated since the first of the year have been made from the Silver Pick lease on the Red Top and it is expected that a shipment will soon be made from the Poffenburger and Dunn lease on the Combination. The Silver Pick worked until January 1 under a five-year sub-lease from the Development and the lessees are now negotiating for a similar lease from the Consolidated. Meanwhile work is being done under a one-year lease, the ordinary term, and three carloads of \$35 to \$50 ore have been shipped, with enough in sight to make several more shipments. Compressed air for the lessees in the Combination and Mohawk is obtained from the Florence. Consolidated lessees work blocks of an average size of 300 by 300 ft. on a royalty basis of 10% of the net return on ore worth up to \$20, 15% on \$20 to

\$40 ore, and 20% on ore over \$40. Lessees are required to work a minimum of 30 shifts per month. Oxidized ore suitable for cyanidation is shipped to the Millers mill of the Tonopah Mining for a minimum of \$1.40 per ton, a special rate made by the Tonopah & Goldfield railroad, and the minimum treatment charge is \$5.25 per ton. The Grandma shaft is 935 ft. deep. It will be continued to 1000 or 1050 and if the east-dipping shale is not entered at about that depth a cross-cut will be driven west to it. The ore recently opened in a raise in the Great Bend is proving erratic in value, the assays varying from \$3.50 to \$75, but ore is being saved for shipment in the raise, which is 25 ft. into the ore-shoot.

RENO.—The precious metals experiment-station of the U. S. Bureau of Mines at the University of Nevada was dedicated recently with prominent Bureau and State officials present. S. C. Lind is in charge of the station. The seventh annual four-week prospectors' short course given by the University of Nevada will end on February 11. Twelve men are taking the course, four miners, a mine operator, two lawyers, a prospector, a real-estate man, a stockman, a machinist's assistant, and a railroad man. The subjects include mineralogy, geology, chemistry, mining law, surveying, and metallurgy.

UTAH

ALUNITE REFINING PLANT IS PROJECTED.

SALT LAKE CITY.—A joint meeting of the local sections of the American Institute of Mining and Metallurgical Engineers, the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Architects, and the American Society of Mechanical Engineers was held at the Commercial Club on the evening of January 27. Edwin S. Carman, who became president of the last-named organization on January 1, gave an address on 'Engineering Opportunities in America's World-Wide Activities'.

Articles of incorporation were filed with the Secretary of State on January 24 by the Utah Alunite Refining Co. The capital stock is \$500,000, divided into 100 shares. The company's holdings consist of eight claims, situated about 16 miles from Richfield and about a mile from Vaca station on a branch of the Denver & Rio Grande railroad. All of the claims contain workable alunite deposits; there is so little overburden that much of the ore can be mined by steam-shovels. Four products are obtained, namely, potash alum, potassium sulphate, aluminum oxide, and aluminum sulphate. There is ample water for milling operations. R. H. Chirgwin, a chemical engineer of New Haven, Connecticut, is president, and Theodore Rodman of Salt Lake City is manager. Among the directors are S. H. Isaacs, a potash expert. It is the intention to erect a mill of large capacity during the coming summer.

PARK CITY.—The work of installing an electric pump in the 1700-ft. level of the Ontario mine has been completed, according to Newton Duñyon, superintendent. This pump, in conjunction with the others already in

operation, will be able to handle 2500 gal. per minute, should it be necessary to do so. The company will now undertake further development work on the 2000-ft. level, the deepest in the mine.

Only three of the local mines are now making regular shipments. In some of the neighboring canyons the snow is from three to seven feet deep, making it impossible to take supplies to the mines and to bring ore down from them. Another factor which is keeping the smaller mines and lessees from shipping is the higher smelting rates

SMUGGLER-UNION MINE, AT TELLURIDE, COLORADO

being asked by the Salt Lake Valley smelters, it being reported that 1921 contracts signed by local lessees provide for a deduction of 5c. per ounce of silver and 2c. per pound of lead, from market quotations, as compared with 3.5c. and 1.5c., respectively, heretofore. During the week ending January 22, the Judge Allied companies shipped 899 tons, Ontario 499, and the Silver King Coalition 541, making a total of 1930 tons.

EUREKA.—A Commercial Club has been organized by the business men of this district; one of the first subjects to be taken up by the organization is the matter of lower freight and smelting-rates on ore. Local mining men feel that there is something wrong when it costs \$1000

and over to ship and smelt a 50-ton car of ore. It is felt that the present freight-rates to Salt Lake Valley smelters are too high, in spite of the fact that the railroads did not increase such rates last August, when the general advance of 25% was applied on all other commodities. It is further the opinion of local mining men that smelting rates should begin to decline, in view of the cut in wages made by the smelters on January 1, and the lower prices of material entering into smelting operations.

Ore shipments from this district for the week ending January 22 totaled 177 cars, of which the Tintic Standard shipped 72; Chief Consolidated, 28; Dragon, 17; Eagle & Blue Bell, 17; Iron King, 17; Victoria, 6; Iron Blossom, 4; Gold Chain, 2; Grand Central, 2; Mammoth, 2; Colorado, 2; Sunbeam, 2; Swansea, 2; Gemini, 2; Centennial-Eureka, 1; Eureka Mines, 1.

The resumption of work at the property of the Tintic Drain Tunnel is under way, according to Frank Birch, local manager for the Knight interests. The company intends to drive a raise through to the surface from a point near the present face of the tunnel. The distance to be driven is about 600 feet.

BRITISH COLUMBIA

COPPER SHIPPED BY BOAT FROM VANCOUVER TO NEW YORK.

VANCOUVER.—The steamship 'Stanley Dollar' is making a special trip by way of the Panama Canal to convey a large consignment of the Granby company's blister copper to New York. It is estimated that the trip will take 28 days. When the blister was sent by rail the average period in transit was 60 days. The Granby is now turning out about 2,750,000 lb. monthly. The Vancouver branch of the B. C. Prospectors' Protective Association has forwarded a resolution to the Provincial Minister of Mines protesting against favoritism in the construction of trails and urging that better protection be provided for prospectors' cabins, caches, and closed mines, and that blasting-powder be provided to prospectors at cost.

VICTORIA.—Retroactive legislation, it is claimed, has made the Nickel Plate mine, at Hedley, subject to the payment of \$70,000 in provincial taxes. G. R. Jones, manager for the Hedley Gold Mining Co., has been in conference with the Government and has suggested that the amount should be halved, on the understanding that the \$35,000 thus released, together with a like amount provided by the company, shall be used in the development of the mine, and in this way help the general unemployment condition throughout the Province.

TRAIL.—The effect of the Consolidated company's new arrangement of paying for custom ore in warehouse-receipts, instead of cash, is shown in the ore receipts for the first two weeks of the year, during which only 13,148 tons was received, of which all but 264 tons came from the company's own mines. The company appears to be curtailing production from its own mines. The following is the output of metals from the smelter during last year, the output for the month of December being estimated:

gold, 42,636 oz.; silver, 1,098,014 oz.; copper, 4,750,000 lb.; lead, 25,723,000 lb.; and zinc, 37,131,000 lb. It will be noticed that, while the preliminary estimates by the provincial Department of Mines credits the Sullivan mine with 70,000,000 lb. of zinc, the Consolidated company only claims a production of 37,131,000. A large proportion of the copper produced at the smelter last year came from the Mandy mine, at Le Pas, Manitoba, and therefore is not credited to this Province.

ONTARIO

REGULATIONS REGARDING OIL-EXPLOITATION ARE TO BE REVISED.

In view of the recent discoveries of oil at Fort Norman on the Mackenzie river the Canadian government has issued an Order-in-Council suspending the regulations regarding petroleum and natural gas in the North-West Territories. It is explained that this is merely a temporary measure, adopted to give the Government an opportunity to consider the whole situation. The permanent policy of the Government regarding oil and gas development in the North-West will be announced in the course of a few weeks before the anticipated rush into the oil country begins. It is understood that those who have already filed on claims will be protected. The order went into operation from January 19.

PORCUPINE.—At a meeting of the shareholders of the Davidson Consolidated, on January 18 it was decided to sell the mine to an English syndicate which has already purchased 1,000,000 shares of treasury stock at 75c. per share and will buy in the outstanding stock in the hands of shareholders at \$1.18 per share. It is intended to reopen the mine on March 1 and proceed with the erection of a 500-ton mill. R. C. Fielding, consulting engineer, who made an examination of the property on behalf of the purchasers, reported that apart from the veins already opened there are great probabilities that further orebodies of profitable grade await discovery. He states that the vein at the 550-ft. level, 19 ft. wide, looked strong and it was safe to assume that the ore would continue to a greater depth. Including 'probable' ore, he estimated the tonnage disclosed by the work done at 350,000 tons, averaging \$11 per ton of recoverable metal. An important orebody has been found at the Dome Mines in cross-cutting at the 1050-ft. level. The width of the vein has not yet been determined but the ore is stated to be richer than that on the upper levels, averaging \$20 per ton.

COBALT.—The leading producing companies are storing their silver bullion in the hope of a rising market. It is officially stated that the Nipissing has nearly \$1,500,000 worth of silver in storage and the Mining Corporation of Canada has also a large quantity on hand.

Good quantities of milling ore in the veins recently discovered on the Bailey and University properties have considerably increased the importance of these finds, which are about 900 ft. apart and both in virgin territory. The Bailey vein has been developed for 60 ft. and carries 5000-oz. ore in some places.

THE NEW YORK MEETING OF THE INSTITUTE

The one hundred and twenty-third meeting of the American Institute of Mining and Metallurgical Engineers is to be held in New York City from Monday, February 14, to Thursday, February 17, inclusive. The annual banquet will be held at the Waldorf-Astoria hotel on the evening of February 16, following a reception to the outgoing president, Herbert C. Hoover, and his successor, Edwin Ludlow, and their wives. There will be the usual technical, social, and entertainment activities.

SAN FRANCISCO SECTION MEETS ON FEBRUARY 8

At the regular monthly meeting of the San Francisco section of the Institute, to be held on February 8, C. M. Eye, who lately returned from the Benguet Consolidated mine in the Philippine Islands, will address the members on 'The Development of the Mineral Resources of the Philippines'. A number of other members who are familiar with conditions in the Islands will join in the discussion. The meeting will be preceded by the regular dinner at the Engineers Club, commencing at 6:15.

SALE OF THE ALICE MINE TO THE ANACONDA COMPANY IN 1911 IS ANNULLED

Minority stockholders of the Alice Gold & Silver Mining Co. won their suit in the Supreme Court to have annulled the sale of that company's properties at Butte to the Anaconda Copper Mining Co. The contention of the minority that the sale was void because the interests controlling the Anaconda company had a monopoly of the copper trade was denied by the Supreme Court. There was nothing to show, the court said, that the Anaconda exercised such control over the market at the time of the sale in 1911.

The minority stockholders claimed that the holders of the majority interest were not authorized to dispose of the holdings against protest of any of the stockholders. The sale was accomplished by the transfer by the Anaconda company of \$1,500,000 of its own stock for the Alice properties, which the lower court held was not justifiable.

The court based its decision on the findings in lower courts that the price was inadequate, and said the fact that no bid was received at a public offering was not evidence that a sale could not have been made at a higher price.

Referring to the contention of the minority that the sale should be annulled because it was negotiated between two corporations having a common membership, the opinion said: "John D. Ryan, at the time of the sale, was president and director of the Alice company; he was also a director and general manager of the Anaconda company. In 1905 he obtained an option on the majority of the Alice company stock for \$600,000 and carried it until purchased by the Butte Coalition company, an Amalgamated subsidiary, of which he was a director, and that company voted a majority of the Alice stock in favor of the disputed sale.

"The record shows beyond controversy that Ryan was the representative of the chief investors in the enterprise; that he dominated the conduct of the practical administrative affairs of the Amalgamated and Anaconda companies, and that he very certainly was in control of the boards of directors of the companies which were parties to the sale of the Alice properties.

"The relation of a director to his corporation is of such a fiduciary nature that transactions between boards having common members are regarded as jealously by the law as are personal deals between a director and his corporation, and where the fairness of such transactions are challenged the burden is upon those who are maintaining them to show their entire fairness, and, where a sale is involved, the full adequacy of the consideration."

The opinion then pointed out that the lower courts had in each case agreed that the price offered for the Alice properties was "inadequate", when their value was considered, and had ordered a public sale before confirming the private transactions.

"Sale under a hammer has come to be synonymous with a sale at a sacrifice," the court remarked in refusing to approve this method of establishing adequacy of consideration offered for the property.

GOLD AND SILVER PRODUCTION OF ONTARIO

The production of silver and gold from the district of Temiskaming since the discovery of silver in Cobalt in 1903; and the finding of gold in the Porcupine field in 1909, has reached a grand total of over a quarter of a billion dollars.

It may be summarized as follows:

Silver	\$191,704,275
Gold	59,760,270
Total	\$251,464,545

Added to this are several million dollars in by-products, making a total of perhaps close to \$260,000,000.

Dividends paid during 1920 compare as follows with 1919:

	1920	1919
Silver mines ..	\$4,058,142.50	\$4,232,241.00
Gold mines ..	3,240,042.42	2,368,039.50
Total	\$7,298,184.92	\$6,600,380.50

Dividends paid by the silver and gold mines of Northern Ontario since 1904 up to the end of 1920 are as follows:

Silver mines ..	\$82,575,940.72
Gold mines ..	18,785,280.20
Total	\$101,360,320.92

In addition to this amount of net profit distributed among the shareholders of the mining companies, about \$4,000,000 may reasonably be estimated to have been earned by close corporations, thereby bringing the total up to \$101,360,320.92.

ALASKA

Hyder.—The cold weather has put the road to the Premier mine in excellent condition. A Holt tractor, drawing four sleighs, is hauling the heavy machinery as far as Nine Mile. Ore is hauled on the return trip. The survey for the aerial tramway has been completed and the work of installation will proceed at once.

ARIZONA

Duncan.—Excavation work for the stamp-mill of the Ash Peak mine is almost completed. Most of the mill machinery is on the ground. It is reported that there is sufficient gold

and silver ore on the dumps to keep the mill in operation for several years.

Humboldt.—Messrs. Lane and Malby of Alamogorda, New Mexico, are arranging details for the removal of a small gold mill from Casas Grandes, Mexico, to their property which is situated near the United Arizona mine 30 miles south of Mayer. —A mill is also being erected at the Gloriana mine at Canyon adjoining the Gillespie property.

Jerome.—J. J. Sweeney, Judge of the Superior Court, has issued an interlocutory injunction in favor of G. A. Kobold, L. J. Selbey, and others restraining M. P. Frasier, G. D. Kase, G. Mitchell, and others from attempting to act as officers and directors of the Jerome-Superior Copper Co. or interfering with Messrs. Kobold, Selbey, and others in their management of the company. The directors and officers enjoined have been charged with mismanagement and with attempting to elect themselves officers of the company at an alleged 'rump' meeting of certain stockholders in December 1920 at Jerome.

CALIFORNIA

Amador County.—The mill of the Central Eureka Co. is crushing ore of excellent grade obtained from the 3900-ft., or lowest, level of the mine. —Operations have been resumed, after an idleness of almost a year, at the Bunker Hill mill. The opening of several high-grade stopes has increased the average mill-heads somewhat.

Eldorado County.—Discovery of rich gold ore is reported from the Grit mine at Spanish Dry Diggings. The south drift from the bottom of the shaft is disclosing good ore, and in the King drift some high-grade has been found. —The American Bar Mining Co. has been incorporated for \$500,000 by San Francisco capitalists.

Humboldt County.—The Electric Metals Co. of San Francisco is said to be planning the construction of an electric smelting plant on Trinidad Bay and is expected to obtain ore from Shasta, Siskiyou, and Trinity counties in California as well as from near-by States.

Lassen County.—The Hayden Hill mill is ready to commence operations. A rich ore-shoot was opened some months ago.

Porterville.—The large deposit of shale situated five miles east of here is to be developed by a company recently organized and known as the California Shale Brick & Tile Co. The company is capitalized at \$400,000. H. W. Lobb, of San Francisco, owner of the property whereon the deposit is situated, heads the corporation. There is said to be 120,000,000 cu. ft. of the ore in sight. This is the largest accessible deposit of shale in California. The company is negotiating for machinery for the plant. Building brick, of the pressed, faced, or common type, also hollow building-tile and irrigation and sewer-pipe will be manufactured. When hard-burned, sample bricks are thoroughly vitrified and impervious to water. Analysis of the shale shows it to contain silica, 68%; alumina, 16%; iron oxide, 4%; magnesia, 2%; lime, 0.58%; alkalies, 1.75%.

Sierra County.—The Mugwump mine, formerly known as the Young America, is being operated by Dennis E. Coughlan, who reports uncovering a deposit of rich gravel.

Trinity County.—A number of good finds have been made on the south fork of the Trinity river. Peter Foley and Charles Cross are reported to have opened a wide vein of good ore in their mine in Carrier gulch. Platinum is reported in the ore being mined by King Brothers on Hasa-yamp creek. The district is handicapped by a lack of cheap transportation.

Tuolumne County.—O. F. Helzer, manager of the Grizzly mine, has sunk the main shaft 150 ft. and drifted on a good vein on the lowest level of the mine. —Figures recently announced by the Carson Hill Gold Mining Co. show that

during the last two years the mine has produced \$2,100,000 in gold from its Morgan mine. This is one of the few properties where operations have been profitable during the period of high cost. As much as 11,000 tons of ore has been crushed in one month in the 20-stamp mill; 10 stamps are being added to increase the capacity.

COLORADO

Cripple Creek.—A new 250-hp. electric hoist has been installed at the No. 2 Last Dollar shaft of the Modoc Consolidated Mines Co. The hoist was designed and built by the Wellman-Seaver-Morgan Co. and is said to be the most powerful electric hoist in Colorado. It is capable of raising a 3-ton skip from a depth of 2200 ft. with a rope-speed of 1200 ft. per minute. The company expects to have 100 miners in its employ by the end of the month. —A carload of gold ore recently shipped by M. J. Rankin, lessee to the Jerry Johnson mine on Ironclad hill, was settled for at the rate of \$120 per ton.

IDAHO

Bonnors Ferry.—Development of the property of the Idaho-Montana Amalgamated Mining Co. is to be started. A long adit will follow the vein which was explored several years ago by means of cross-cuts and drifts from a deep shaft sunk from a point near the outcrop. Lead-silver ore has been found in the workings.

Coeur d'Alene.—Frederick Burbidge, general manager for the Federal Mining & Smelting Co., declared recently that the orebody on the 2000-ft. level in the Morning mine is the most important body of ore uncovered for years. Work of sinking the shaft from the 1800 to the 2000-ft. level was started four years ago and a station was cut on the 2000-ft. level. Drifting both east and west from the shaft developed an ore-shoot 800 ft. long, with a width of 27 ft. In some places the shoot is 35 ft. wide. In most of the older Coeur d'Alene mines the lead ore became base with depth but the Morning appears to be an exception. The ore on the 200-ft. level contains less zinc than any ore that has been taken out from below the 800-ft. level. The new orebody is 1200 ft. below the main tunnel-level of the mine. There are five levels, at 1800, 1600, 1400, 1200, and 1000 ft., between the recent discovery and the collar of the shaft.

The old Monarch property at Murray will be operated by lessees. A lease has been taken on all the levels between the 700 and 1100-ft. levels, including all of the mine equipment.

—The Brady Development Co., operating the Rose claims and the Olympia group under lease and bond, will soon resume work in extending the long cross-cut tunnel from the Headlight into the Brady claims. These claims, situated between the Tamarack and Greenhill groups, two of the richest properties in the Coeur d'Alene, were taken over a year ago under a lease and bonded by a syndicate headed by Patrick Brady. A shaft 100 ft. deep revealed ore similar to the Tamarack. Tunnel-rights were obtained on the old Headlight tunnel and a cross-cut was started to tap the ore in the Rose claim.

According to reports the Bunker Hill & Sullivan company is employing 1200 men in the mines, mills, and smelters; the Morning mine has 500 men; the Hercules company employs 500 men in its mine at Burke and its mill at Wallace; the Hecla company, with a mine at Burke and mills at Gem and Wallace, is employing 400 men; the Tamarack at its mine at Nine Mile district and the mill at Frisco in the Burke canyon, employs 200 men. It is estimated that 500 additional men are employed in the smaller mines. No protest came from the men when the recent wage cut of \$1 per shift was announced. The men at the mines in the Coeur d'Alene are now being paid wages averaging \$4.50 to \$4.75 per day.

Kingston.—At the Hypotheek mine, near here, a small crew of men is driving a new cross-cut adit in the direction

of a second lode. The work has advanced 300 ft. and within a short time the vein should be cut. Stringers cut recently show more mineralization than before and indicate the proximity of a vein.

MONTANA

Butte.—A bill has passed the Montana legislature favoring a resolution requesting Congress to impose a tariff of not less than one cent per pound upon imported manganese ore.—No. 3 shaft at the Butte & Superior mine has now reached a depth of 2530 ft. The shaft is in the Rainbow lode at this point, the ore running from 10 to 40% zinc. To date, no indications of any considerable change in the metal content of the ore from zinc to copper have been noted.

Cooke City.—G. L. Tanzler, general manager for the Western Smelting & Power Co., says that the smelting plant near here is 90% complete. The copper blast-furnaces at the plant will have a capacity of 300 tons per day. The

Divide.—It is reported that George Wingfield will resign as a director of the Tonopah Divide at the annual meeting to be held on March 2 and that Clyde A. Heller, president of the Tonopah Belmont, will be elected a director.

Goldfield.—Two carloads of \$35 ore were shipped from the Silver Pick lease on the Red Top mine of the Consolidated company, and Matt Murphy, superintendent, expects to continue shipments at the rate of two cars per week.

Klondyke.—A 7-ft. width of \$60 silver-gold ore is being entered by the Knox Divide. A winze has been sunk in ore 15 ft. from the 60-ft. level.

Ploche.—Shipments of silver-bearing fluxing ore from the Black Metals mine to the Salt Lake Valley smelters are being increased. New equipment has been installed and the mine is in better condition than ever before. It is expected to reduce the cost of mining, which has been \$4.15 per ton, to \$3 per ton, according to Jack Gilmer, manager of the mine.

Tonopah.—The first bullion shipments for the new year

SILVER KING MILL AT PARK CITY, DESTROYED BY FIRE ON JANUARY 27

company already has a hydro-electric plant on the Clark-ford river four miles from here. A working-tunnel has been driven to cross-cut the orebodies in the mine on Henderson mountain two miles from the smelter.

Helena.—A second shaft, 2000 ft. west of the present one, will be sunk at the Willard mine in the Warm Springs district.

Libby.—The first shipment of ore from the Lukens-Hazel mine has gone to the East Helena smelter. A 200-ton concentrator is in operation at the property, where 100 men are employed.

Nelhart.—Thomas Westgard, in charge of the Silver Dyke property on Copper creek, will drive a tunnel to explore the vein opened in the Marion shaft at a lower level. Indications in the shaft promise the opening of a large deposit of low-grade ore.

Lessees are mining good ore in the Moulton mine, but a sufficient quantity to warrant starting the mill has not been obtained.

NEVADA

Carson City.—Dixon Bros., lessees of the Southwest Comstock property, have opened high-grade ore. Ore obtained from development work is being shipped.

from the Tonopah mills were as follows: Tonopah Belmont, 83,000 oz. valued at \$91,300; Tonopah Extension, 50,910 oz. valued at \$56,000; West End Consolidated, 48,600 oz. valued at \$53,460. At the Tonopah Extension progress is being made in sinking the McKane shaft, which has now reached a depth of 1470 ft. At the 1540-ft. point connection will be made with the Victor shaft, thereby providing better facilities for developing the western section of the mine. The company has not yet completed the station on the north side of the Victor shaft at the 1880-ft. level, but cross-cutting has been started toward the Merger, Victory, and Murray veins.—A. E. Lowe, mine manager for the North Star Co., has shipped a 50-ton carload of ore to the McNamara mill that returned \$28.06 per ton. Progress is being made in driving the cross-cut on the 700-ft. level toward the Belmont workings. Arrangements have been made to connect the two mines.

West Divide.—A 2-ft. width of \$200 to \$300 ore has been opened in a drift driven south from a new cross-cut on the tunnel-level of the West Divide. This is the first ore found on the tunnel-level.

NEW MEXICO

Socorro County.—Tin has been found about 30 miles

west of Fairview and Chloride, and 80 miles east of Mogollon on Taylor and Diamond creeks near the Sierra county line. The formation is rhyolite reefs or dikes, 500 to 800 ft. wide, all impregnated with tin with traces of platinum in some places. Stream tin is found in the creek beds. The country has no good wagon-roads, but there is plenty of wood and water. The New Mexico Tin & Metals Co., whose main office is at 67 Liberty street, New York, J. R. Murphy, president, has a tunnel in 360 ft. in ore.

OREGON

Rogue River.—The Ancient River Goldmining Co. is operating in the old channel of the Rogue river, about half a mile south of the town of Rogue River. The company has put in a 6-in. Byron Jackson centrifugal and a 6-in. S-type Allis-Chalmers pump, direct connected to a 75-hp. motor and delivering direct into a No. 1 giant. The bank of the river was worked for miles 30 years ago with good results. The bottom of the present river is conglomerate which runs up at a low angle under the bank, then lays flat for a few feet, when it dips steeply into the old channel. Great wealth is reputed to lie in this old channel, but the present workings are not sufficiently advanced to estimate values beyond showing that gold and platinum are present, and the gravel ranges to over 20 ft. in thickness, with a loose sand overburden, averaging about 6 ft. The usual difficulty of separating the fine gold from black sand is present. J. S. Taylor is manager.

UTAH

Park City.—Fire originating in the boiler-room at the Silver King Coalition mill on January 27 destroyed the concentrator, transformer-house, ore-bins, and part of the snowshed leading to the main shaft. The mill has a daily capacity of 300 tons. It was constructed in 1899 and has been in almost constant use since that time. It has been remodeled several times and recent tests with oil-flotation have given good results. The loss is completely covered by insurance, and the company proposes to replace the plant with a more modern mill. The loss is estimated at \$100,000, but a large part of the machinery can probably be salvaged. High-grade ore will be mined and shipped as usual, so that the income will not be materially reduced nor will a great many men be thrown out of work. Forrest Mathez is superintendent at the property and John Tallon is superintendent of the mill.

MEXICO

Monterrey.—Mining operations in the States of Coahuila and Zacatecas are more active notwithstanding the depression of the metal markets. Several of the larger and well established companies are making preparations for increasing their production, notable among these is La Esperanza company, which has its general offices in Saltillo. This company has recently increased its capital stock 50,000 shares, the new capital being used to expand production and make improvements. In the Santa Rosa mountains near Monclova, Coahuila, Santiago Cardenas is opening up a new group of mines containing silver, lead, and zinc ores. The San Marcos Mining Co. is preparing to begin extensive development work upon its mine in Coahuila, as is also the Perlita Mining Co. The Jimulco Mining Co. which has for many years yielded rich returns for its American owners, who live in San Antonio, is also enlarging the scope of its development work. Jesus Aguilar recently filed on five claims near the mine of the Jimulco company in the Jimulco district.

Many Americans are coming into Mexico for the purpose of investigating mines with a view to making investments in desirable properties. They are finding travel perfectly safe and they are going into the more remote camps under the same security against personal harm that obtained during the peaceful days of the administration of the late President Porfirio Diaz, it is stated.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Morton Webber is at Salt Lake City.

O. B. Perry has returned to New York.

E. T. McCarthy writes from Shui Chow, in China.

George D. Nickel, of Denver, was in San Francisco last week.

Milnor Roberts has been visiting the mines of the Mother Lode in California.

Gomer P. Jones, general manager for the Hedley Gold Mining Co., B. C., is at Los Angeles.

Robert Clarke, of Denver, was in San Francisco on his way to Grant's Pass, Oregon.

James Frame, of Boston, is examining some silver properties near Chalchihuites, in Zacatecas, Mexico.

A. E. Wells, of New York, formerly of the U. S. Bureau of Mines, was here last week on his way to Anaconda.

Walter Harper, of the Anaconda Copper Mining Co., has been visiting the Eureka mine at Sutter-Creek, California.

George C. Riser, superintendent of the Nevada Consolidated Copper Co.'s concentrator at McGill, was at Salt Lake City recently.

Harold A. Linke, mining engineer of Salt Lake City, has accepted a position with the Compania de Real del Monte y Pachuca at Pachuca, Mexico.

W. Lorrain Cook is now assistant superintendent for the Utah Salduro Co. at Salduro, Utah, where the company is engaged in the production of potash.

R. H. Channing, president of the Utah Consolidated Mining Co., is at Salt Lake City inspecting the company's mines and new concentrating plant in Pine Canyon.

C. H. Munro sailed on the 'Creole State' from San Francisco for the Federated Malay States on February 3. He will be resident manager for the Yukon Gold Company.

Arthur J. Hoskin, recently appointed geologist and engineer for the Colorado United Mines Co., has been spending most of the winter at the mines near Wall Street, Colorado.

Blanford C. Burgess has resigned his position as chief engineer for the Iron Cap Copper Co., Globe, to become managing director of the Adjut Mining Co., at Winkelman, Arizona.

OBITUARY

Benjamin Bowden Lawrence died of pneumonia on January 21 at his home, in New York, where he was born 63 years ago. After graduating from the Columbia School of Mines, in 1879, he went to Colorado, and, in due course, became manager of several notable mines. Afterward, for eight years, he maintained an office as consulting engineer at Denver. In 1901 he went to New York, where he remained in consulting practice for the rest of his life. As a boy he was assisted by a bursary while at Columbia University, and he took pains in later years to give similar help to young fellows not able to pay their way. He was an enthusiastic supporter of his alma mater and took a special interest in the School of Mines. The value of his advice was duly recognized by his being elected first a representative of the alumni on the board of trustees and then a life member of the board, always working in close co-operation with his friend, President Butler. Ben. Lawrence had a wide circle of friends among those engaged in mining and to them his cheery presence was always most welcome; he was of a co-operative, helpful, genial temperament, and assisted willingly in any effort to further the best interests of the profession. Many of us in the West mourn his loss deeply and will cherish the memory of his friendship always.—T. A. R.

THE METAL MARKET

METAL PRICES

San Francisco, February 1

aluminum dust, cents per pound.....	65
antimony, cents per pound.....	9.50
copper, electrolytic, cents per pound.....	13.75-14.00
lead, pig, cents per pound.....	6-8
platinum, pure, per ounce.....	\$65
platinum, 10% iridium, per ounce.....	\$95
quicksilver, per flask of 75 lb.....	\$50
pelter, cents per pound.....	8.25
tin dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

January 31.—Copper is inactive but steady. Lead is quiet and easy. Tin is stagnant and lower.

SILVER

Below are given official or ticker quotations for silver in the open market distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND MARKETS

There is a more confident feeling throughout the country and developments since the first of the year support improved sentiment. The gradual liquidation in many directions has materially lessened the strain on bank resources and the general credit position is improving, says 'Commerce Monthly'. However, the importance of export demand in the marketing of many American products makes it inevitable that present unstable financial conditions throughout a large part of the world will be reflected in the United States for some time to come. In addition, the readjustment from wartime price levels to those of a more normal character has been progressive and has affected different commodities in turn. While it has been practically completed in some lines, a further series of readjustments must necessarily occur in others before business can be properly re-aligned to new conditions and each has its bearing on the entire situation. The effect of these successive readjustments should neither be an occasion of general pessimism nor should undue optimism be engendered by unrelated improvement in special localities or lines of business.

The reserve ratio of the Federal reserve banks now stands at 48.1% as compared with 42.7% at the middle of October, when the fall requirements were at a maximum, and with 45.1% a year ago. Money rates, which continued at the levels previously current until well after the beginning of the new year, have now become somewhat easier. The ruling rate on commercial paper has declined from 8 to 7%, with a limited supply available and an active demand from country banks. Rates on bank acceptances have likewise declined sharply under the influence of liberal buying. The volume of time-loans on securities has been small, while the rate has declined from 7% to 7-6%. Call-loans made on the Stock Exchange ranged from 7 to 6%, while private sources were reported as having made loans as low as 4%.

Government requirements will be heavy and the needs of industry will continue large as liquidation progresses. Meanwhile, although bank borrowings from the reserve institutions have been reduced below the maximum reached last October, they are still substantially in excess of those of a year ago.

During the closing weeks of December, fluctuations in the principal exchanges were nominal. After the beginning of the new year, sterling advanced abruptly from 3.55 to 3.75, on the 11th. Following this rapid recovery, it has declined somewhat, closing the period at 3.73%. Other European exchanges with the exception of Italian lire, which were weak throughout, tended to follow the lead of sterling. The Scandinavian exchanges advanced steadily and substantially during the month; continuing the improvement which they experienced during the preceding period.

The pressure of bills against exports of grain and other raw materials has been relieved, the surplus of grain having the period under review is indicated in the following table of rates for cable transfers:

		Week of	
		December	January
Par		16.22	16.22

France, cents:	Cable	6.95
	Demand	6.97
Lire, cents:	Demand	3.64
Marks, cents		1.55

Eastern Metal Market

New York, January 26.

There is almost no activity in any of the markets. The price tendency is downward in most of them.

The copper market has turned dull and a little weaker. Prices have eased.

Prices of tin are lower, due largely to a sharp decline in London. Buying by dealers has been good.

The lead market is very quiet and slightly easier, but not weak.

Demand for zinc is insignificant and values are lower.

Antimony is a little higher.

Two metals, copper and tin, are now quoted lower in London than since 1913.

IRON AND STEEL

After four weeks of restricted operation, amounting in some cases to almost complete shut-downs, various independent steel companies are starting up on orders that will keep their plants going on a 50% scale for two weeks or more.

Thus the Chicago district shows better operations than in several weeks, the independent companies running this week at 30 to 40% of steel works and 50 to 60% of blast-furnace capacity, while the Steel Corporation's finishing mills were at 80 to 85%.

While the lowering of wages is much discussed, the steel companies are slow to act, the reductions thus far made affecting a relatively small minority of mill-workers.

The dullness of the pig-iron market has been somewhat relieved by sales amounting to about 12,000 tons of various grades in the Philadelphia district and transactions of moderate size in the Central West. Prices as low as \$27.50, Birmingham, have been done on a sale of 2000 tons to one company, but the usual quotation in the South is now \$30, which is \$2 lower than that prevailing a week earlier.

American exporters are actively canvassing home consumers as possible buyers of European steel and are also trying to sell such steel in distant markets, such as the Dutch East Indies. As yet home buyers are as indifferent to this foreign material as they are to American steel. German steel is offered in increasing amount, though sometimes hidden through handling by British, Belgian, or Dutch exporters.

COPPER

The market has turned weak and is easier than at any time this month. There was a fair demand the latter part of last week but it appears that there was some competition for the business offered which resulted in some cutting and therefore a withdrawal of buyers. Despite this, a fair business was done. Electrolytic copper is now quoted at 12.75 to 13c., New York, for prompt and January, with first-quarter delivery held at 13 to 13.25c. Lake copper is in light demand; it is quoted at 13.25c. for early delivery.

In the British market conditions are extremely poor with prices down below quotations in 1913, although the previous low point is stated to have been in March 1915.

TIN

The feature of the market is the sharp decline Monday and yesterday in the London market. Prices broke sharply on Monday, an average of £8 per ton, or back to the previous low point in 1915. In fact it is stated that higher prices than those now quoted prevailed in all of 1913 and early 1914. Yesterday spot standard fell to £164 per ton with future standard at £169 15s. and spot Straits at £187. This is a decline from last week of £9 in spot Straits and almost £16 in standard. In sympathy with this decline the New York market is lower, spot Straits being quoted yesterday

at 32.50c., New York, against 34.75c. a week ago. The market has been fairly active, dealers being the buyers. Consumers are still uninterested. From the buyer's point of view, the market has been a narrow one because there are few dealers ready to sell. A good volume of business has been done but the transactions have been put through quietly and all attractive offers have been quickly taken. The business done has consisted mostly of February-March delivery here, shipment-metal for that position being hard to purchase. Arrivals thus far this month have been 955 tons with 2110 tons reported afloat.

LEAD

This market is dull and the undertone is easy, but there are no signs of weakness. There is the ever-present possibility of softness due to imports if the London market declines sufficiently, but the strong tone of exchange is apparently neutralizing any decline there. Admittedly there has been good buying of lead recently and hence the quiet market now is natural. There is a comparative scarcity of prompt lead in the East which has resulted in some premiums on this position. The leading interest continues to quote 4.75c., New York and St. Louis, but the outside market now stands at 4.80c., St. Louis, or 5 to 5.10c., New York.

ZINC

There is a total absence of activity and prices are largely nominal. Domestic prime Western is quoted at 5.40c., St. Louis, or 5.85 to 5.90c., New York, but imported metal is quoted, duty paid, at around 5.50 to 5.60c., seaboard. The London market is being closely watched for its effect here. The possibility of foreign competition is a cloud on the horizon. Producers are not forcing the market and are selling only enough to keep their organizations intact, though some are pressing their product slightly. They claim there is no profit at present prices but a decided loss and are advocates of a tariff. Any sales made for importation are subject to a possible increase in the tariff.

ANTIMONY

The future shipment market is higher, according to advices from the Orient. Wholesale lots, duty paid, are as a result higher here at 5.50c., New York, with jobbing lots at 5.62½ to 5.75 cents.

ALUMINUM

The market is unchanged with the leading producer asking 28.30c. f.o.b. producer's plant for wholesale lots of virgin metal for early delivery, with other sellers asking 23.50 to 24.50c., New York, for the same brand.

ORES

Tungsten: There is not much chance of a tariff on tungsten getting through the present session, according to sentiment in the trade. Market feeling is better, however, since those holders anxious to sell at \$3 per unit at the beginning of the year refuse this base now. The lowest price mentioned lately has been \$3.25, but buyers are not interested.

Molybdenum: The market is devoid of activity and prices are nominally unchanged.

Manganese: A spot lot of almost 2000 tons, probably resale, is understood to have been sold at 30c. per unit. The market is quiet with quotations from first hands nominal at 35 to 40c. per unit.

Manganese-Iron Alloys: Some British and American producers of ferro-manganese are quoting \$100, seaboard, and \$105, delivered, respectively, but no sales are recorded. Resale is reported done at \$90 to \$93, delivered, but some is held at \$95, point of shipment. Spiegeleisen is inactive at \$40 to \$45, furnace.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

HEADLIGHTS FOR MINE-LOCOMOTIVES

Westinghouse mine-locomotive headlights have been designed to meet a demand for fixtures which are sufficiently rugged to stand up under the hardest possible operating conditions, and yet which carry the lamp on a spring suspension which will adequately protect the filament from breakage due to vibration and jars. The special features of these headlights which enable them to meet the above requirements are as follows:

1. The frame, case, and cover are made of high-grade cast-iron, heavy enough to withstand a terrific amount of abuse without injury.

2. The lens-holder is fitted to each case with a threaded

Headlights for Mine-Locomotives

3. The case (which contains the socket and lamp) is entirely suspended from six springs. These springs oppose each other and are always in tension. Thus, the spring-suspension is equally effective in all directions, assuring longest possible lamp life.

4. A socket is provided for medium-base lamps of from 15 to 94-watt capacity. These lamps should be of the concentrated filament type, which are made for use on circuits from 105 to 130 volts. The headlights may, therefore, be used in multiple on 105 to 130-volt circuits, or two in series on 210 to 260-volt circuits.

5. The reflector is made of heavy copper, silver plated. Its parabolic shape ensures proper re-direction of the light rays.

Where headlights are to be operated on circuits of more than 260 volts a resistance is required. The resistance is

housed in a full cast-iron case and cover with open grid sides and top. This housing is very sturdy, being far superior in this respect to the sheet-steel housing usually furnished. Within the box are mounted two 50-watt, 600-ohm resistortubes. The resistance, therefore, is capable of dissipating 100 watts and has a total resistance of 1200 ohms.

SHOVELING MACHINES

'Mucking' is an important and costly detail of mine operation. A machine that will take the place of human hands will reduce greatly the cost of mining, provided the machine is more efficient and is able to spend its time on the job instead of in the repair shop. During the past few years shoveling machines have been brought much nearer to perfection. It is probable that within the next year there will be one or more efficient machines on the market.

Several machines suitable for use in cross-cuts and drifts in metal mines have been brought to our attention. Among them is the Armstrong shoveling machine, called the 'Shoveloder', made by the Lake Superior Loader Co., Duluth, Minnesota. The digging end of this machine consists of a scoop, or shovel, which is propelled into the muck-pile by air power, and then upward and back over the machine to the car to be loaded. It requires 6 ft. 10 in. of head-room. Reports have been received of its successful operation at several places.

The Hoar shovel, made by the National Iron Co., of Duluth, has the appearance of a miniature steam-shovel. It is said to be sturdy and fast in operation. One of these machines has been supplied to the United Comstock mine at Gold Hill, Nevada. A report of its performance will be forthcoming at a future date.

The McDermott twin-scoop loader, made by the Wellman-Seaver-Morgan Co., of Cleveland, Ohio, picks up rock by means of scoops on an endless chain, dumping onto a conveyor-belt, which delivers to the car at the rear.

There is in course of construction by the Denver Rock Drill Co. a shoveling machine invented by Howard Denis, for many years employed at the Empire mine, Grass Valley. This machine should be on the market within the next two or three months. It works on a different principle from those described above, having a series of rakes, or strong projections on an arm, which draw the rock onto a conveyor-belt. The conveyor-belt carries the rock back of the machine to the car. This machine has been demonstrated at the Empire mine and looks promising.

Within the last few weeks another machine has been demonstrated at the Empire mine, and plans for its manufacture are now afoot. This machine has no digging device, but consists essentially of a conveyor-belt which operates from the foot of the muck-pile. One or two men pull or shovel the rock onto the conveyor, which carries the rock

back of the machine to the car. A feature of this loader is the supplying of power for operating the conveyor-belt through the medium of the conveyor-roller. At a recent test underground at the Empire mine, six cars were loaded and switched out in 35 minutes. A 16-cu. ft. car was loaded in one minute and fifty seconds on the surface, two men using shovels. This machine is the invention of R. E. Tremoureaux, formerly superintendent of the Champion mine at Nevada City, California.

The above facts are set forth with a view to bringing before superintendents the advisability of the study of the shoveling machine. A letter to the manufacturers named will bring the necessary details.—Monthly Bulletin of the Metals Exploration Co.

COMMERCIAL PARAGRAPHS

'Pump Data No. 53' is the title of the latest catalogue issued by the **Aldrich Pump Co.**, of Allentown, Pa. Chilled-iron plungers and patented metallic packing are the particular products dealt with.

The **Chicago Bridge & Iron Works**, builder of elevated tanks, storage tanks, and all classes of plate-metal work, announces the opening of a sales office in San Francisco at 232 Rialto Bdg., of which **Frank L. Cook** will have charge.

Georgé L. Hurst, formerly manager of the dredging department of the **Bethlehem Shipbuilding Corp., Ltd.**, San Francisco, has resigned his position with that corporation and has taken up general mechanical engineering with offices in the Balboa building.

The **Adamson Manufacturing Co.**, East Palestine, Ohio, has added a new department for manufacturing all kinds of storage, pneumatic and pressure tanks, welded pipe, battery-casings, evaporators, condensers, and a large line of arc-welded products.

Bulletin No. 15-C, recently issued by the **National Tube Co.**, of Pittsburgh, is an unusually instructive treatise on special features of oil-well drilling equipment, much of which is included in the products manufactured by the company. An article by **A. G. Wolf** describes the 'Rotary Method of Well-Drilling', and points out the advantages and disadvantages of the method.

The **Hardinge Company** announces that on and after January 1, 1921, **V. A. Stout**, formerly in charge of its Salt Lake City office, becomes general sales manager and will be in its New York City offices at 120 Broadway. **W. L. Penick**, formerly in Salt Lake City and later in charge of the Hardinge Company's branch office at Spokane, comes to Salt Lake City again as district sales manager in charge of all the company's business in the West.

The **Chicago Pneumatic Tool Co.** announces the appointment of **R. F. Eissler** as assistant to the vice-president with headquarters in the company's new office building at 6 East 44th St., New York. **W. C. Straub**, formerly district manager of the New Orleans branch, has been appointed district manager of the Pittsburgh branch to succeed **Mr. Eissler**, and **Ross Wyeth**, formerly attached to the Pittsburgh branch, has been appointed district manager of the New Orleans branch to succeed **Mr. Straub**.

Irvin S. Thyle, a member of the **A. H. Simpson Co.** since its organization, has purchased the interests of **A. H. Simpson** in that company and also in the Triangle Engineering Co. **Simpson** is leaving the machinery business to engage in handling silica products. There will be no change in the business name of the Simpson company. Hereafter, in addition to overhauling and rebuilding machinery, the company will engage in the manufacture of screens, elevators, and transmission machinery.

Arrangements have been made by the **Union Miniere du Haut Katanga** with the **Garred-Cavers Corporation**, for the

use of its process, whereby pulverized coal is used to replace coke in blast-furnaces. The **Union Miniere du Haut Katanga** has placed orders for a 42-in. Fuller mill and a Fuller-Kenyon pump for the coal-preparation plant which will be used in connection with the above process at its copper smelter in the Belgian Congo. Licenses were secured from the **Garred-Cavers Corporation** some time ago by the **Cerro de Pasco Copper Corporation**, Peru, the **International Nickel Co.**, and the **Tennessee Copper Co.**, for the use of this process at their various smelters.

D. E. Sawyer has been re-elected general sales manager for the **Pollak Steel Co.** for the year 1921 and is located, as in the past, at the New York office of the company. **S. K. Morrow**, formerly manager of operations, is now manager of sales for the three plants, with offices at Cincinnati works. **C. G. Talbott**, formerly assistant manager of operations, is now manager of rolled products for the Marion plant. **A. C. Wehl**, for several years superintendent of Cincinnati plant, is now general works manager in charge of operations and productions of the Cincinnati, Chicago, and Marion plants. **V. W. Prather**, formerly cost auditor for Cincinnati plant, is now general cost auditor of three plants. **R. A. Mitchell** takes the position vacated by **Mr. Wehl** to become superintendent. **J. H. Deickman** becomes manager of materials and inspection of three plants. **W. P. Woods** becomes auditor and **G. H. Tallaksen**, superintendent of the Chicago plant.

Until recently it has been the custom to wash coal with jigs, cone-washers, or other methods, in the use of which advantage is taken of the difference in specific gravity between the refuse and the pure coal. In general these methods have proved satisfactory on the larger sizes, but are highly inefficient on the small material both with regard to cleanliness of product and saving of the fine coal. The **Deister-Overstrom coal-washing table**, manufactured by the **Deister Concentrator Co.**, was designed to overcome the difficulties experienced with jigs and similar methods in the treatment of the smaller sizes of coal, especially that which will pass through a 1-in. perforation down to the finest dust. That this table is highly efficient on the class of material mentioned is attested by the fact that it is possible to eliminate 90% or better of the removable impurities, and at the same time reduce to a minimum the loss of good coal in the refuse.

'Oil-Line Pumps' is the title of a recent publication by the **Aldrich Pump Co.** The pumps discussed are of a group especially constructed and adapted for oil-line service, representing the latest developments in oil-pump design. In pumping oil through a pipe-line, the working-pressure is caused by the friction of the oil passing through the pipe. The velocity of the oil, its viscosity, and the length of the line and the size of the pipe determine the pressure. The safe working-load of the pipe used would correspond, of course, to the maximum pressure. These conditions are based upon a uniform flow of oil through the pipe. Any variation in velocity above or below a pre-determined rate causes unnecessary friction. Therefore, to force a maximum amount of oil with a given working-pressure, the velocity of the flow must be as nearly uniform as possible. The **Aldrich quintuplex pump** lends itself to this work, since the total variation in the discharge is only 7%, as compared to a variation of 23% from the triplex and a variation of 45.6% from the duplex double-acting pump. It is obvious that the quintuplex is a mechanical improvement on the other types. Moreover, it has the advantage in distributing the strains of the crankshaft, gearing, and connecting-rods in a uniform and regular way, thereby lessening shocks and undue wear. Each plunger has an independent and interchangeable fluid end whereby the size of the casting is greatly reduced, thus increasing the factor of safety in operating against the high pressures necessary.

NOTES	Page 213
INSTITUTE AFFAIRS	214
Comments on the management of the Institute of Mining and Metallurgical Engineers; its contrast, in point of numbers, to the Mining and Metallurgical Society of America; and the urgent need for some restriction of effort in order to secure some measure of efficiency.	
LEAD SALTS AND PLAGIARISM.....	215
An instance of wholesale borrowing in contemporary technical literature; with the result that credit was not given where credit was due.	
INTERNATIONAL FINANCE	216
A study of the economics of import and export. The need for the financing of credit abroad, possible in view of our sound financial position. Congestion due to the accumulation of raw materials and goods can best be relieved by a realization of the fact that the retention of both the goods and the money in this country is a poor policy.	

DISCUSSION

INSTITUTE AFFAIRS	
By W. A. Borchardt	217
Institute publications. Mistake of encroaching on field better served by technical journals. Politics and engineering.	
INSTITUTE EXPENDITURE	
By George E. Collins.....	218
Condensation of Institute publications necessary. Failure of headquarters staff to extend courtesy to visiting members.	

ARTICLES

BRAHAM LINCOLN	219
An address delivered on the occasion of the unveiling of a statue of Lincoln in London last year.	

LEAD SALTS IN THE CYANIDATION OF SILVER ORES

By Ralph W. Perry.....	221
A critical study of the action of lead salts, the soluble-sulphide theory, the action of soluble sulphides, and the effect of artificial sulphides. The comparative value of litharge and lead acetate.	

HEAP LEACHING OF COPPER ORES AT BISBEE...

	225
Details of a 3-year leach of copper ore. The methods to be adopted by the Copper Queen branch of the Phelps Dodge Corporation.	

KARL EILERS V. GUGGENHEIMS.....

	226
A statement, in the form of a letter to the stockholders of the A. S. & R. Co., which accompanies the usual annual request for proxies, and is circulated for the purpose of discrediting the assertions made by Mr. Eilers.	

RADIO-ACTIVITY AND SOME PRACTICAL APPLICATIONS

By C. W. Davis.....	229
A monograph on radium, its discovery, properties, detection, and estimation, with notes on radio-active elements and self-luminous compounds.	

A METHOD OF RECORDING GEOLOGY IN DEVELOPMENT WORK

By C. Erb Wuensch.....	223
A system of classification of geological specimens, with special reference to facility to connect them with the position of the deposits they represent, as indicated in the mine plans.

EASTERN METAL MARKET	246

Putting on the Brakes

IN THESE days of unusual demand and dislocation of normal conditions in many lines of industry, the natural position of the seller is to follow a line of progressive price advances. These advances usually far exceed those warranted by higher costs of production. Human nature dictates that when a market is completely in the hands of the seller, as it is in many raw or manufactured materials at the present time, the obvious course is the most advantageous one, namely, that the price should be all that the traffic can bear.

Sound business policy frequently runs counter to natural impulses. Understrained price advances, no matter if the continuing demand appear to be so strong, as to justify them, eventually reach the point where they shut off buying for the reason that the ultimate consumer cannot stand the cost. There is a maximum point beyond which to advance prices is to impose an undue burden upon one party and to threaten the good of the whole trade, since, after all, the best interests of buyers and sellers are interdependent. Large steelmakers are giving due recognition to this truth by throwing their influence against any further general advances in their lines of manufacture.

The wisdom of holding prices in check when radical advances are possible admits of ready recognition. To reduce them under present conditions, however, represents a much more striking example of broad-gauged business management. This is the policy which the Linde Air Products Co., leading manufacturer of oxygen, has had in effect since the beginning of the war. This company bases its action upon the belief that, in the long run, the good will and friendship that will accrue will more than offset any increased profits to be gained from higher prices in a temporary market. The practical results netted by such a policy, approaching as it does the altruistic in business, no doubt will be watched with keenest interest by the general manufacturing world.

from the IRON TRADE REVIEW
May 18, 1916

A policy, an editorial and a chart

DURING the days of war when things were being turned upside down The Linde Air Products Company maintained its standards of uniformly pure quality, comprehensive service and low price.

While prices of other essentials were mounting up towards the peak the average price of Linde Oxygen was reduced, and, through the most trying period of the war, continued practically on an

even keel. This splendid record was made possible by the great volume of business accorded to Linde by manufacturers and other oxygen users the country over.

A continuation of this generous patronage will enable Linde to make more effective its unchanged policy of supplying American Industry with oxygen of the highest purity, anywhere, in any quantity and at the lowest possible price.

The Largest Producer of Oxygen in the World

T. A. RICKARD, Editor

GOVERNOR HARRING of the Federal Reserve Board says that a general revival of sound business and industry is to be expected in the near future. We believe it.

RUMORS of a sale of four hundred million pounds of American copper to foreign consumers, principally Germany, by the Copper Producers Association, have been insistent in New York. The financing of this deal involves an outlay, it is said, of \$40,000,000, subscribed by a syndicate, the membership of which is not all in New York. This is an item of news that we hope to see confirmed, for it would go far toward relieving our market of its surplus stock of metal.

ON another page we celebrate Abraham Lincoln's birthday by publishing the full text of the oration delivered by Mr. Elihu Root on the occasion of the unveiling of the statue at Westminster last summer. It is fitting that Lincoln should be memorialized in front of the abbey in which lie the dead not only of England but of the forefathers of our republic, going back to a time that makes 1776 seem but yesterday. Moreover, if the American nation had given the world nothing more than the person and character of Abraham Lincoln it would have justified its separation from Great Britain.

NEW 'silver' coins, produced as a result of the passage of the Coinage Act of 1920, are already in circulation in Great Britain. They are similar in size and design to the old coins, but, owing to the large amount of nickel used in their manufacture, are considerably harder. The actual silver fineness of the new coins is 500 per 1000, as compared with 925 per 1000 in the old coins, which are being withdrawn from circulation. The last depreciation in the standard of British silver coins, to 250 parts per 1000, occurred during the reign of Edward VI, the restoration being effected during Queen Elizabeth's time.

WE went to press last week too soon to be able to make any reference to the celebration of the 35th birthday of our contemporary and neighbor, 'The Journal of Electricity'. A specially handsome issue of the 'Journal' and a sumptuous banquet served fittingly to commemorate the auspicious occasion. We were privileged to participate in the gastronomic part of the affair and to share the mental stimulus transmitted by a number of speeches from leaders of the electrical industry on

this Coast. The occasion and the speeches, however, represented a good deal more than the electrical business and profession, for both of them gave expression to the invincible optimism and the unfailing initiative of the leaders of industrial finance and engineering education in California. Mr. Robert Sibley, the talented editor of 'The Journal of Electricity', and his friends of the McGraw-Hill Publishing Company are to be congratulated on the event and upon the delightful way in which they gave it appropriate emphasis.

TRADITIONAL customs die hard in England, but sometimes the ceremonial observed on State occasions has to be modified to suit changing conditions. An instance of this was observed last month in London on the occasion of the Feast of the Epiphany when, according to annual custom, King George sent a couple of Court officials to the Chapel Royal, St. James's Palace, with gifts of gold, frankincense, and myrrh, to be handed over with the observance of proper ceremonial to the officiating dignitary. Now, gold is out of circulation in England, and the appearance of the Court officials at the high altar of the Chapel with a roll of 'Bradburys', as the English currency-notes of small denomination are called, would have been distinctly out of place. The ceremonial called for actual gold, real frankincense, and fragrant myrrh. The resins were obtained without difficulty, but to find the needed gold, some newly-minted sovereigns had to be withdrawn from the Bank of England. But frugality is the order of the day in England at the present time; and, at the conclusion of the ceremony, a roll of notes was exchanged for the gold, which was then duly returned to the vaults of the bank.

RELIEVED of the effusion of reportorial fancy, the bare facts concerning the career of a recent visitor in Seattle, as told in the 'Post-Intelligencer', make a remarkable story: Born in Ireland in 1847; emigrated to the United States a few years later; rounded the Horn in a sailing vessel and arrived in San Francisco about 1860; spent several years in Virginia City in the days when the Comstock was in its glory; sailed for Victoria, B. C., in 1874 and at once organized a party for the relief of miners in the Cassiar district, who were threatened with death from scurvy; 'came out' after two years and found diversion by running a store in Tombstone, Arizona, when the town offered a real thrill almost every hour; joined the vanguard to Dawson during the gold-rush of 1897; took \$100,000 out of Bonanza creek; settled later

at Nolan in the Koyukuk mining district, 480 miles by dog-team from Fairbanks; and now, at the age of 74, calls that home. This, gentle reader, is a skeleton of the story of Miss Nellie Cashman. We omitted the pronoun for a good reason. If richness of experience, if service to mankind, if the esteem of hundreds in a land like Alaska, where sham is at a discount and true worth counts most—if these things go to make a successful life, this excellent woman can look back over the past 70 years with the utmost satisfaction. She expects to return to Koyukuk to assume the position of deputy U. S. Marshal for her district. Hers is a career that might well be the envy of many a masculine sourdough.

REGULATIONS heretofore affecting the disposal of privileges in oil-producing areas have been temporarily suspended by the Canadian government. Apparently the unexpected discovery of oil near Fort Norman in the Mackenzie River region, indicating the possibility of a highly important oil-bearing terrain, has taken the Government off its feet; the authorities with commendable caution have 'called time' for a brief interval during which they expect to weigh the situation and determine what changes in the regulations are advisable. The large companies, who are willing and able to spend the money necessary to explore and develop the oil resources, urge that they be accorded some measure of protection from those who would file on adjoining claims with no intention of prospecting the ground but with the hope of extorting an unreasonable price in the event that oil be discovered. They feel that precedence should be given them as to land in the immediate vicinity of their drill-holes, and point out that the present regulations make no such provision. Some who oppose monopoly of resources by a few large private companies favor the nationalization of the oilfields and the construction of a government-owned system of pipe-lines. This would give the small operator an opportunity to drill under government lease, and to market his product economically. Another problem faced by the officials is that of controlling a possible stampede into the Northwest Territory next spring. Unless properly equipped and safeguarded, prospectors would risk suffering and even death in a journey northward during the brief summer season. The one well that gushed oil recently was capped immediately, so that there is no way of knowing what the output may be; nor is there assurance of the existence of anything more than an isolated oil-bearing formation, so that the present excitement may prove to be much ado about nothing, especially in view of the fact that the climate and isolation of the district prohibit exploitation on any but an ambitious and systematic scale.

AN excellent example of the useful perpetuation of a mining enterprise by the extension of its industrial activities to "fresh fields and pastures new" is given by the Yukon Gold Company. This undertaking was organized in 1908 to exploit the gold-bearing gravel of the Klondike river and its tributary creeks near Dawson, in the Yukon Territory. When it became apparent that the

ground was approaching exhaustion, the management began to look around for fresh alluvial deposits to which to apply the dredges. These were as good as new because the wearing parts had been replaced continually. Not long ago eight were at work in the Yukon, two in Alaska, and four in California. Now the two in Alaska are idle and three only are operating in California, namely, on the American, Trinity, and Yuba rivers. Thus ten dredges bought at pre-war prices and in good working shape were available. In 1918 the tin placers of the Malay Peninsula were suggested as deposits to which the dredges might be transferred profitably; so Messrs. Charles H. Munro and John F. Newsom were sent out at the head of a prospecting expedition, with such favorable results that four different areas have been acquired, by option or purchase, after careful drilling. Mr. Munro estimates that in the areas already selected there are 126 million cubic yards of gravel averaging 83 pounds of 73% tinstone per yard, representing a yield, in concentrate, of 75 million pounds of metallic tin, from which an operating profit of eighteen to twenty million dollars may be anticipated. Three dredges are in course of reconstruction and the first should start digging next June. The tables of the gold-saving apparatus are being replaced by sluices, the collecting area for saving the cassiterite being double that provided for arresting the gold. It looks like a good venture; certainly the engineers in charge are thoroughly competent. Moreover, dredging for tin in the Malay States is nothing new, the first work of the kind having been started nine years ago. Several English companies have done well, notably the Renong, under the guidance of Mr. E. T. McCarthy. Malaya produces 40% of the world's output of tin.

Institute Affairs

We publish a couple of letters, one from Virginia and the other from Colorado, on the management of the Institute. They are representative of other letters that we have received, but not for publication. In the main we agree with Mr. W. O. Borchardt, but we think him mistaken in identifying the management with a coterie in New York; on the contrary, it seems to us that ample evidence has been given during recent years of a desire to place Western members on the board of directors and even in the presidential chair. Unfortunately the chief financial centre of the United States is not centrally situated; likewise the national legislature meets in a city on the same side of the continent; so that the head office of the Institute is necessarily at a distance from many important mining and metallurgical centres. The directorate must be selected from those able to be in frequent attendance. As to the social activities, these also are shared chiefly by the eastern membership, because the annual meeting is usually held in New York, but an effort has been made, successfully, to distribute the summer meetings to other parts of the country. We agree with our correspondent that the talk of engineering efficiency is somewhat ludicrous in the face of the financial condition of the Institute, particularly in a year

during which an engineer world-famous for administrative ability has been the president of the Institute; but that only emphasizes the fact that the management is not in the hands of the presidents, whose tenure of office is short and who therefore are unable to make themselves felt in that regard, but in the hands of the secretary and his staff. All professional organizations in the last resort depend for their administration upon their secretary and those whom he selects to assist him. During Dr. Raymond's time we had an incomparable editor, but a poor business-man, as secretary. Since then we have had a poor editor, but, we thought until recently, an excellent man of business. Dr. Raymond ran the whole show: he was the real president, and those whom he selected to fill the titular post were actually only vice-presidents. Since his resignation, the presidents have been selected in a more systematic way and they have been more representative of the active part of the profession, but the growth of Institute membership and therefore the extension of its business affairs has been so great as to overtax those in direct control. Indeed, we belong to a minority that views the numerical bigness of the Institute with no enthusiasm. The contrast with the Mining and Metallurgical Society of America is instructive. This society in its effort to be select has succeeded in being exclusive, so that it has a membership of something like 300, in comparison with the 8000 in the Institute. Evidently opinions differ in the ratio of 80:3 as to who is fit for membership in a professional organization of mining and metallurgical engineers. We believe that both societies go to an extreme; in other words, that the American mining and metallurgical profession would be properly represented by about 3000 or 4000 men in good standing and suitable for membership in a professional organization that aimed to establish any sort of criteria for ability and character. It may be said that a generous comprehensiveness is more in accord with the democratic idea, and to that argument we can make no cheerful rejoinder, because we believe in widening the usefulness of any agency of education and we would regret to shut the door upon men, especially young men, who are seeking to make the very most of their opportunities; but, as a practical matter, it cannot be doubted that the swelling of the Institute by intensive solicitation, as has been the custom of late, leads to a membership so large that management becomes increasingly costly and inefficient. The complaint voiced by Mr. George E. Collins is echoed by others who have been impressed, or depressed, by the atmosphere of the head office. The lack of pleasant amenities and the failure to obtain personal courtesy at the office is, of course, a consequence of the mechanical methods inseparable from an overgrown organization. In the old days, a member had no difficulty in meeting Dr. Raymond, who welcomed him as a friend and made the visit memorable. In those days the Institute had 3000 members and published one volume per annum. A remedy is obvious. Let the Institute cease to attempt to cover the whole field of mining and metallurgy; there is an Iron and Steel Institute; why should not those engaged in the coal and iron branches of industry enroll them-

selves where they belong? Why should our Institute try so persistently to swell its membership from among those who ought to be members elsewhere? Mere bigness, mere numbers, means nothing and leads nowhere in particular. The solidarity of our Institute, and its usefulness, we believe, would gain by restriction to the mining of minerals other than coal and the metallurgy of metals other than iron, leaving those fields of activity to a society already organized to take care of them.

Lead Salts and Plagiarism

On another page of this issue we publish an article by Mr. Ralph W. Perry on 'Lead Salts in the Cyanidation of Silver Ores'. The subject has received attention in our previous issues, and several monographs of technical value have appeared, written by Messrs. M. W. von Bernewitz and G. H. Clevenger, among others. In this connection we regret the necessity for correcting a statement in Mr. Perry's paper, in which he credits Mr. W. A. Fahrenwald as the author of three conclusions with regard to the function of lead salts in the wet metallurgy of gold and silver. The chapter in Mr. Fahrenwald's book, 'The Cyanide Process', to which Mr. Perry refers, is an unblushing plagiarism of Mr. Clevenger's article, 'The Function of Lead Salts in Cyaniding', which appeared in our issue of October 24, 1914; and the credit for the conclusions belongs, therefore, to Mr. Clevenger and not to Mr. Fahrenwald. But Mr. Clevenger is not the only victim, for 'The Cyanide Process' is little more than an undigested collection of abstracts, for the most part unacknowledged, from Rose's 'Metallurgy of Gold', Collins' 'Metallurgy of Silver', MacFarren's 'Cyanide Practice', and the writings of other well-known authorities. It is regrettable, not only that credit should be denied where credit is due, but that engineers should be so easily misled into thinking that because material appears in book-form it is, necessarily, authoritative. Mr. Fahrenwald obtained his data from a number of reliable sources, but his book shows all the earmarks of having been prepared in a slovenly and unscientific manner; the copious extracts from well-known treatises have not even been edited to conform to a standard. Apart from the information correctly collated from reliable textbooks the significance of which has not been emasculated by crude and inexperienced paraphrasing, there is practically nothing of worth in the volume. Where an occasional sentence or paragraph is obviously original the construction is usually so involved as to make it meaningless. In other instances, where it must be admitted that the writer of the treatise speaks with an appearance of authority, it is found that he is repeating, almost word for word, the published opinions of experienced metallurgists. A glaring example of this appears in the chapter on 'Metallurgical Tests' where positive views on a particular phase of metallurgical work, published in the 'Mining and Scientific Press' in 1912, appear, almost word for word as in the original, as the personal opinions of the author of the book. Mr. Fahrenwald has grossly violated all the recognized laws of professional etiquette

among technical investigators by the wholesale abstraction of the writings of others, usually indicative of careful research and unselfish effort, without giving credit where credit is due. A general acknowledgment of indebtedness in the preface savors of impertinence, and only serves to accentuate the fact that his unmitigated plagiarism was not unintentional. The copyrighting of such a book, as has been done by the author, is nothing less than a farce. We suggest to our readers and contributors that they disregard the volume as a serious contribution to the technical literature of the subject.

International Finance

Announcement is made that "foreign finance to the extent of \$150,000,000 or more is expected by Wall Street bankers to be well under way within the next six weeks". Our foreign trade in 1920, it is also announced, reached a total value of 13½ billion dollars, this being the largest in the country's history. Exports amounted to 8½ billions and imports to 5½ billions, leaving a trade balance of three billions. The Department of Commerce, which issues these statistics, states that exports were one-third greater than in 1913 and imports were nearly three times those of the ante-bellum period. We imported 429 millions of gold and exported 322 million dollars. During 1920 about 275 millions of European finance was consummated on the American money market, and at the present time about 375 millions of new European business is said to be in sight, not counting probable applications from Canada. The relative vigor of our money market is indicated by the prompt over-subscription to the Belgian loan of \$30,000,000. France is expected to make a large borrowing at an early date, and other European countries, including Switzerland and the Scandinavian kingdoms, are preparing to 'touch' us. Besides these demands there is every probability that as soon as the question of German reparations is settled there will be a funding of these obligations with a view to borrowing money upon them. Those who are well informed do not view with any alarm the prospect of the United States becoming a creditor to an increasing extent; on the contrary, provided the danger of another world conflagration or widespread revolution can be obviated, they consider it inevitable that we should accept the onus of the favorable position in which the War has placed us. At the present time we have, so to speak, both the money and the goods; this makes it impracticable for us to do business with our customers, the nations overseas, unless we extend our credit to them. We are in a position to do so. This country was never so sound financially. As compared with a year ago the reserves of the Federal Reserve system have increased from 45% to 48%. As Mr. W. P. G. Harding, governor of the Federal Reserve Board, has stated recently: "It is of vital importance that our trade with Europe be continued, and it is of scarcely less importance that trade relationships of other countries with Europe be maintained". If not, there will be a constant tendency toward the accumulation here of goods, principally raw materials, because countries that

formerly sold to Europe are unable now to do so, on account of Europe's inability to pay, and therefore are compelled to ship their products to the United States to sell for cash. The War Finance Corporation and the Edge Act are meant to expedite our foreign trade under the existing adverse conditions. It will be recalled that in December at Chicago a meeting of financiers approved a plan for a corporation to be organized under the Edge Act with a capital of 100 million dollars and able therefore, it is estimated, to finance a billion dollars' worth of business with Europe. Mr. Harding, of the Federal Reserve Board, is the president of this corporation, which is called the Foreign Trade Financing Corporation. This move was approved generally because it set aside the less desirable method of utilizing the resources of the Government for relieving the stringency in foreign credit, it being held rightly that Government aid usually leads to extravagance and waste on the part of the governments on the other side. Moreover, the cost of Federal assistance in this direction would fall eventually on the taxpayers, instead of such transactions being conducted by means of corporate enterprise, with all the care and economy inseparable from enlightened self-interest—in other words, on a business basis. As Mr. Herbert Hoover said: "We must face the fact that the economic ills we suffer arise from vicious economic circles that can be broken in one way only, that is, by the establishment of credits abroad, not the dangerous short-time credits in which we are already over-extended, but the long-time investment in reproductive enterprise abroad. The War has brought to us a great new phenomenon in our international economic life, that not for a long time to come, and perhaps never again, can we establish our foreign trade upon a balanced intake of commodities assisted by minor factors of remittance and service. If we would give full-time employment to our farmers, our laborers, and our business men, we must be prepared to invest abroad some part of the value of those surplus products." That is what Great Britain did on a large scale, much to her gain and prestige, in the years before 1914. It is true, soon after the Armistice, we heard the counsels of the parish pump, urging us to keep aloof from Europe and her distress, and to go forward alone in our wealth and prosperity as if we were an island in mid-ocean untouched by the sorry plight of the world at large. Those parochial counsels are now appraised at their value; they came from ignorance and they appealed only to ignorance. During the last twelve months the wiser advice of experienced economists and wide-awake financiers has put the issue squarely before us. We must buy if we want to sell; if our customer cannot pay in gold or its equivalent, we must extend credit; it is foolish to think that we can export unlimitedly while erecting a wall of tariffs against importation. These are the axioms of international trade. Moreover, existing conditions afford us a great opportunity to take a sagacious as well as a beneficent leadership in the restoration of the world's commerce, upon which in the end depends its political and social welfare. Let us fulfill our destiny with a clear head and a courageous spirit.

DISCUSSION

Institute Affairs

The Editor:

Sir—Your editorial and the letter entitled 'Institute Affairs' in your issue of January 22 are timely and to the point. It seems probable that a majority of the members of the Institute will agree with the opinions and recommendations therein contained, but this majority is generally silent at the very time when it is most important that it express itself, and consequently errors and abuses creep in that are eventually corrected by upheaval, whereas, taken in time, they could have been corrected without disturbance.

It is perhaps natural that the management of the affairs of the Institute should be largely in the hands of the older members, and particularly in those of such members as live in New York. Such men have generally gone high in the profession, and are sufficiently detached from the daily grind to be able to give time for what amounts to public service. The Institute is, however, now too large for them to give more than consultative and supervisory attention to its affairs, and all the details must be left to a paid staff.

While this system would appear to give the Institute the benefit of the best experience and most mature judgment in the direction of its affairs, it unfortunately seems to be one that lends itself to degeneration into management by a small group, which, although actuated by the best of motives, and believing itself to have the best interests of the Institute at heart, yet is quite out of touch with the mass of members, and governs in a way that is scarcely democratic. Apparently this governing group considers of the Institute as the primary entity, instead of remembering that it is merely the means to the ends which the members have associated themselves to effect. This habit of thought, which unconsciously puts the cart before the horse, similarly caused the leaders of Prussia to think in terms of the State instead of in terms of the associated individuals who alone gave that mechanism its reason for being.

"All that the rank and file want of the Institute is the regular publication of carefully edited technical papers." It seems impossible successfully to contradict this statement, and if it were to be taken literally by the management and applied as the criterion on any existing or projected activity of the Institute it seems probable that not only would present causes of discontent and objection vanish, but it would be found easily possible for the Institute to live within its income.

It is certainly inconsistent to campaign for more mem-

bers, so that the activities of the Institute can be "extended", while at the same time passing the hat to those already members to re-pay the loss resulting from present "over-extension". Disregarding the social activities, which are participated in by so small a minority of the members as to be immaterial, I believe it to be true that any member of the Institute can at the present time derive more benefit from subscription to three technical periodicals than from his membership. Most of the papers now published by the Institute, if they have real value, would be published, probably in better edited condition, by these technical periodicals, did the Institute not exist. The Institute's journal, 'Mining and Metallurgy', is not a technical magazine—it is a mistake.

The remark you credit to Captain J. C. Ray is certainly just, and your correspondent, quoted above, expresses the same opinion, that, before urging participation by engineers in public affairs as a palliative of the ills of society, the engineers should demonstrate their ability successfully and economically to manage their own professional public interests, even to their own satisfaction. This we are certainly not at present accomplishing through the medium of the Institute, but perhaps if we go at it the way we think we would run the Government if only given a chance, we may succeed, and may also gain experience that will be useful in the bigger job.

This thing of the importance of getting the engineers to show how well they could succeed in Government where the 'politician' is supposed to have failed, is being run into the ground, and is becoming a public joke. Before tackling the task of operating the United States, why not start with a single city, or even a State? Probably there is nowhere a greater concentration of engineers of all kinds per square mile or per capita than in New York City and State, but do we there see them demonstrating how well engineers individually and collectively can bring their influence to bear in support of efficiency and economy in government? Has not New York State just lost by "requested resignation" the services of its engineer Commissioner of Roads, who was also in charge of road-building for the A. E. F., in order to make a place for a professional politician whose present soft snap is to be abolished as a sop to retrenchment; and has anyone heard the deadly roar of the outraged associated engineers which might naturally have been expected to follow so raw a deal?

What is so often overlooked is that in a government such as ours all other qualifications for participation in public affairs are useless to the individual ambitious thus to shine unless he has them as additions to the primary

and major ability to guess what it is that the people want, and, by co-operation with others, secure it for them. The people never say beforehand what they want, and so the politician has to try to guess. If he guesses right and is able to secure action, he leads. If he guesses wrong he soon finds out. What is the use of condemning the politician? He gets results under conditions where most of us would fail.

Perhaps what we most need in the Institute is not the engineer in politics, but some politics applied to engineering. Maybe we do not make our wants properly known, and we need a politician who will guess what they are and get them for us. Perhaps if given a chance we might even take enough interest in our own affairs to fill out a questionnaire, the results of which would serve as a guide to the authorities of the Institute in the reconsideration of the functions and activities of the Institute which appears to be indicated.

W. O. BORCHERT.

Austinville, Virginia, January 27.

Institute Expenditure

The Editor:

Sir—I wish to associate myself, in the main, with the expression of 'A Member', and also with the editorial on this subject, in your issue of January 22.

I have heard on all sides numerous expressions which indicate that the Proceedings of the Institute are considered too voluminous; and I believe they would be more generally useful if they were condensed. I also agree in thinking that the magazine, 'Mining and Metallurgy', is not worth its cost.

As to the running expenses, it is perhaps easier for us in the precious-metal mining business, who have been struggling with adverse conditions for several years, to realize the necessity for strict economy than for those who have been surrounded by the prevailing atmosphere of New York extravagance. Yet I think that a more considerate and unselfish attitude on the part of those who conduct the affairs of the Institute might have been shown.

During a recent visit to New York I called at the offices of the Institute, mainly to evince interest in its affairs, but partly for two other purposes:

(1) To be identified, so as to cash bank-drafts which I had with me for expenses.

(2) To enquire the way to the office of your New York contemporary.

In (1) I was not successful, because neither the Secretary nor Assistant Secretary was there. In (2) I was equally unsuccessful, because none of the young ladies who were in charge of the office (and who did not appear to have much to do) had the least idea of the whereabouts of the office of the 'Engineering and Mining Journal' or how to get there. What is more, with one exception, they did not seem in the least to care. The attitude toward the visiting member seemed to resemble that of certain office-buildings which display conspicuous placards reading "Book Agents and Solicitors not ad-

mitted to this Building". The general air of lack of occupation and indifference was such as might naturally create an unfavorable impression on the mind of the out-of-town member whose contributions assist to maintain what, I fear, is an establishment better calculated to uphold the dignity of the Institute than to fulfil its real needs.

GEORGE E. COLLINS.

Denver, January 24.

On Prospecting

The Editor:

Sir—Referring to Mr. Everit in 'M. & S. P.' of January 8, page 41, will say it behooves me as a prospector to encourage the mining engineer and prospector to join hands; the time has come when the prospector needs assistance, and his first aid is the mining engineer. The old-timer may be a little rough and uncouth, yet be a congenial companion. The young student must give and take, and if he can make clear any given point, unless the old man's head runs up like a thumb, he will be grateful.

My experience has taught me that the young engineer who is willing to do things and has the courage of his convictions is an asset to the prospector. There is but little virgin country to be prospected in the United States, except, of course, the district of Alaska. I venture to say, however, the field is nearly as large as ever on account of the increased demand for the rare minerals and the thousands of prospects in every stage of development having fair geological futures. There is just as good picking for the experienced prospector and engineer as there was a few years ago for the tenderfoot. As has been said before in the 'M. & S. P.', the mining man must help to develop new mines. If we continue to mine we must dig.

A PROSPECTOR.

Congress Junction, Arizona, January 20.

MANGANESE DI-OXIDE is often used for neutralizing the green tint produced by the presence of iron in glass, according to a Bureau of Mines publication. Pre-war specifications usually required 80 to 85% of MnO_2 and less than 1% of iron. Carbonaceous pyrolusite is objectionable, but the silicious variety is permissible. Powdered ore is usually employed where the glass is made in pots, while the lump or granular variety is frequently employed when tanks are used for the melting. The amount of manganese di-oxide added varies from 2 to 15 lb. per 1000 lb. of sand in the batch. An ornamental black glass has been produced by adding about 3% of the ore to the glass mixture. Manganese di-oxide is also used in the preparation of purple glazes and enamels. Manganese di-oxide, either natural or artificial, is extensively used as a 'dryer' for linseed and other oils. The quantity added rarely exceeds 0.5% but it is stated that even this amount tends to darken the oil; this objection, however, does not hold in the case of certain salts of manganese, such as sulphate, borate, oxalate, resinate, and linoleate, which are also largely used.

Abraham Lincoln

The address delivered by Mr. Elihu Root on the occasion of the unveiling of the St. Gaudens statue, the gift of America to the British people, at Westminster, on July 28, 1920

Abraham Lincoln was born on February 12, 111 years ago, in a log cabin among the mountains of the State of Kentucky. He came into a frontier life of comparative poverty, labor, hardship, and rude adventure. He had little instruction and few books. He had no friends among the great and powerful of his time. An equal among equals in the crude simplicity of scattered communities on the borders of the wilderness, he rose above the common level by force of his own qualities. He was sent by his neighbors to the State Legislature, where he learned the rudiments of government. He was sent to the Congress at Washington, where he broadened his conceptions to national scope. He was admitted to the Bar, and won a high place as a successful and distinguished advocate. He became convinced of the wickedness of African slavery, that baleful institution which the defective humanity of our fathers permitted to be established in the American colonies. He declared his conviction that slavery was eternally wrong with power and insistence that compelled public attention. He gave voice to the awakened conscience of the North. He led in the struggle for freedom against slavery. Upon that issue he was elected President. In that cause, as President, he conducted a great war of four years' duration, in which millions of armed men were engaged. When in his wise judgment the time was ripe for it, then upon his own responsibility, in the exercise of his authority as commander-in-chief, invoking the support of his country, the considerate judgment of mankind, and the blessing of God upon his act, he set free the 3,000,000 slaves by his official proclamation, and dedicated the soil of America forever as the home of a united liberty-loving commonwealth. The act was accepted; it was effective; African slavery was ended; the war was won—for union and for freedom; and in the very hour of victory the great emancipator fell at the hand of a crazed fanatic.

It was not chance or favorable circumstances that achieved Lincoln's success. The struggle was long and desperate, and often appeared hopeless. He won through the possession of the noblest qualities of manhood. He was simple, honest, sincere, and unselfish. He had high courage for action and fortitude in adversity. Never for an instant did the thought of personal advantage compete with the interests of the public cause. He never faltered in the positive and unequivocal declaration of the wrong of slavery, but his sympathy with all his fellow-men was so genuine, his knowledge of human nature was so just, that he was able to lead his countrymen without dogmatism or imputation of assumed superiority. He carried the civil war to its successful conclusion with

inflexible determination; but the many evidences of his kindness of heart toward the people of the South and of his compassion for distress and suffering were the despair of many of his subordinates, and the effect of his humanity and considerate spirit upon the conduct of the war became one of the chief reasons why, when the war was over, North and South were able during the same generation to join again in friendship as citizens of a restored Union.

It would be difficult to conceive of a sharper contrast in all the incidental and immaterial things of life than existed between Lincoln and the statesmen whose statues stand in Parliament Square. He never set foot on British soil. His life was lived and his work was wholly done in a far distant land. He differed in manners and in habits of thought and speech. He never seemed to touch the life of Britain. Yet the contrast but emphasizes the significance of the statue standing where it does. Put aside superficial difference, accidental and unimportant, and Abraham Lincoln appears in the simple greatness of his life, his character, and his service to mankind, a representative of the deep and underlying qualities of his race—the qualities that great emergencies reveal, unchangingly the same in every continent; the qualities to which Britain owed her life in the terrible years of the last decade; the qualities that have made both Britain and America great. He was of English blood, and he has brought enduring honor to the name. Every child of English sires should learn the story and think with pride: "Of such stuff as this are we English made". He was of English speech. The English Bible and English Shakespeare, studied in the intervals of toil and by the flare of the log fire in the frontier cabin, were the bases of his education; and from them he gained, through greatness of heart and fine intelligence, the power of expression to give his Gettysburg address and his second inaugural a place among the masterpieces of English prose.

He was imbued with the conceptions of justice and liberty that the people of Britain had been working out in struggle and sacrifice since before Magna Charta—the conceptions for which Chatham and Burke and Franklin and Washington stood together, a century and a half ago, when the battle for British liberty was fought and won for Britain as well as for America on the other side of the Atlantic. These conceptions of justice and liberty have been the formative power that has brought all America, from the Atlantic to the Pacific, to order its life according to the course of the common law, to assert its popular sovereignty through representative govern-

ment—Britain's great gift to the political science of the world—and to establish the relation of individual citizenship to the State, on the basis of inalienable rights which governments are established to secure. It is the identity of these fundamental conceptions in both countries which makes it impossible that in any great world emergency Britain and America can be on opposing sides. These conceptions of justice and liberty are the breath of life for both. While they prevail both nations will endure; if they perish both nations will die. These were Lincoln's inheritance, and when he declared that slavery was eternally wrong, and gave his life to end it, he was responding to impulses born in him from a long line of humble folk, as well in England as in America, who were themselves a product of the age-long struggles for the development of Anglo-Saxon freedom.

The true heart of Britain understood him while he lived. We remember the Lancashire workmen brought into poverty and suffering through lack of cotton. When the Emancipation Proclamation had dispelled all doubts as to the real nature of the struggle in America, 6000 of them met in a great hall in Manchester and sent to President Lincoln a message of sympathy and support. This was his answer:

"Under these circumstances I cannot but regard your decisive utterances upon the question as an instance of sublime Christian heroism which has not been surpassed in any age or in any country. It is, indeed, an energetic and re-inspiring assurance of the inherent power of truth, and the ultimate and universal triumph of justice, humanity, and freedom. I do not doubt that the sentiments you have expressed will be sustained by your great nation; and, on the other hand, I have no hesitation in assuring you that they will excite admiration, esteem, and the most reciprocal feelings of friendship among the American people. I hail this interchange of sentiment, therefore, as an augury that, whatever else may happen, whatever misfortune may befall your country or my own, the peace and friendship which now exist between the two nations will be, as it shall be my desire to make them, perpetual."

We may disregard all the little prejudices and quarrels that result from casual friction and pinpricks and from outside misrepresentations and detraction, and rest upon Lincoln's unerring judgment of his countrymen and his race. We may be assured from him that, whenever trials come, whenever there is need for assurance of the inherent power of truth and the triumph of justice, humanity, and freedom, then peace and friendship between Britain and America will prove to be, as Lincoln desired to make them, perpetual. This man, full of sorrows, spoke not merely for the occasions and incidents of his own day. He expressed the deepest and holiest feelings of his race for all time. Listen to the words of his second inaugural:

"Fondly do we hope, fervently do we pray, that this mighty scourge of war may soon pass away. Yet, if God wills that it continue until all the wealth piled by the bondsman's 250 years of unrequited toil shall be sunk,

and until every drop of blood drawn by the lash shall be paid by another drawn with the sword, as was said 3000 years ago, so still it must be said: 'The judgments of the Lord are true and righteous altogether.' With malice toward none, with charity for all, with firmness in the right as God gives us to see the right, let us strive on to finish the work we are in; to bind up the nation's wounds; to care for him who shall have borne the battle, and for his widow and for his orphan; to do all which may achieve and cherish a just and lasting peace among ourselves, and with all nations."

Consider this letter which he wrote to Mrs. Bixby of Boston:

"I have been shown on the files of the War Department a statement of the Adjutant General of Massachusetts that your are the mother of five sons who have died gloriously on the field of battle. I feel how weak and fruitless must be any word of mine which should attempt to beguile you from the grief of a loss so overwhelming; but I cannot refrain from tendering to you the consolation that may be found in the thanks of the Republic they died to save. I pray that our Heavenly Father may assuage the anguish of your bereavement, and leave only the cherished memory of the loved and lost, and the solemn pride that must be yours to have laid so costly a sacrifice upon the altar of freedom."

More than half a century has passed, but is this the voice of a stranger to the men and women of Britain in these later years? Because, under the direst tests of national character, in the valley of the shadow of death, the souls of both Britain and America, prove themselves of kin to the soul of Abraham Lincoln, friendship between us is safe; and the statue of Lincoln the American stands as of right before the old Abbey where sleep the great of Britain's history.

SULPHURIC ACID, according to the Bureau of Mines, is used for the following purposes: Dilute acid, that is, 60°B., 78% H_2SO_4 , or weaker, is used in the manufacture of superphosphates, ammonium sulphate, and sulphates of magnesium, aluminum, iron, zinc, and copper; in precipitating barium and calcium sulphate for chemical purposes; in the manufacture of various mineral and organic acids; in pickling sheet-iron for tinning and galvanizing; in the production of copper, zinc, silver, nickel, and gold; for various types of galvanic batteries, storage batteries, electroplating; in the manufacture of ether; in making and purifying many organic coloring matters; in making starch, syrup, and sugar; and in numerous other chemical and metallurgical operations. Concentrated acid, that is, acid 60°B., 78 to 100% H_2SO_4 , is used for purifying benzene, petroleum, paraffin oil, or other mineral oils; for manufacture of nitroglycerin, pyroxylin, nitrobenzene, picric acid, and various other nitric compounds and nitro ethers; and in the manufacture of fatty acids by distillation. Fuming acid (oleum) is used principally for the manufacture of various forms of explosives, certain organo-sulphuric acids, and in fortifying weaker acids.

Lead Salts in the Cyanidation of Silver Ores

By Ralph W. Perry

INTRODUCTION. The beneficial action of lead salts in the cyanidation of gold ores was recognized shortly after the process was introduced on the Rand; and in 1893 J. S. MacArthur and C. J. Ellis obtained patents covering the use of these reagents in the cyanide process. At that time little advantage was gained from their use, for the reason that cyanidation was applied only to gold ores, but as soon as the process proved successful in extracting silver as well as gold the importance of using lead in some form in the solutions became apparent. It has since been employed generally in the treatment of silver ores; indeed, ores are rare in the treatment of which an increased extraction cannot be obtained from the use of lead salts. Generally where it is not used, the ore itself contains enough oxidized lead minerals to make further addition superfluous. No satisfactory explanation of the action of lead has yet been advanced.

THE SOLUBLE-SULPHIDE THEORY. The value of lead salts was first believed to consist in their ability to precipitate soluble sulphides from the solutions as insoluble lead sulphide, thus preventing the re-precipitation of silver already dissolved. This theory was conditional on the formation of soluble sulphides by the action of cyanide solutions on silver sulphide or other base-metal sulphides. Some doubt has been expressed by numerous authorities¹ as to the formation of soluble sulphides, and they have shown quite conclusively that soluble sulphides are rarely found in cyanide solutions. It would be most surprising if they could be detected in solutions containing the amount of silver and zinc that is usually present in plants using zinc precipitation. E. M. Hamilton states that they have been found in the effluent solutions from aluminum precipitation at Nipissing and Divisadero, owing probably to the reduction of thio-sulphates in the precipitation process.

The solution of silver from silver sulphide or from argentite, the form in which it is found most frequently in nature, is often expressed by the following equations:

Since the reaction in the first equation is reversible, it would furnish a reasonable explanation of the action of lead salts, if it actually took place. Soluble sulphides can exist in cyanide solutions, depending on the strength of the solution and the amount of silver and sulphides present, but it does not seem reasonable to expect a solution of a given strength in cyanide to dissolve silver, and for the soluble sulphides formed then to precipitate it

from the same solution. It can be easily understood that a condition of equilibrium would be reached where no more silver could be dissolved and extraction would stop unless the strength of solution were changed, and either silver or the soluble sulphides were removed. The second equation explains why the continued solution of silver is possible with the same strength of solution through the continuous removal of the K_2S formed by its conversion to KCNS, but in the absence of any evidence of its existence it seems more reasonable to accept one equation only as explaining the reaction, that is:

In aerating the sand charges at the Homestake mine by blowing compressed air through them, thiosulphates are found in the effluent solutions if water washes follow the aeration; but sulphocyanates are found if cyanide solution is applied first. This conversion of thiosulphates to sulphocyanates would be expected, according to the same reaction as is employed in the quantitative determination of thiosulphates.² In my article I make no mention of soluble sulphides being found in either the water washes or the cyanide solutions used and they were presumably absent. Thiosulphates are often found in cyanide solutions and are probably produced directly from some of the base-metal sulphides in the ore, under the oxidizing conditions prevailing in cyanide work, but there seems to be no direct evidence that soluble sulphides are formed in the treatment of most ores. In the first test recorded in Table I, stannic sulphide was used and K_2S was present in the solutions at the end of agitation but was not detected earlier. I attribute this to the reduction of the stannic sulphide to the stannous form with the simultaneous liberation of the extra molecule of sulphur.

Notwithstanding the fact that the formation of soluble sulphides is generally doubted, this explanation is repeatedly employed to account for the use of lead salts. A. W. Fahrenwald³ says: "There are three reactions which prevent the formation of soluble sulphides. (1) Zinc taken into solution during precipitation seems to be as effective for their removal as lead added intentionally. (2) Sulphides rapidly form sulphocyanates with the simple alkaline cyanides which are always present, as

(3) Alkaline sulphides rapidly oxidize to thiosulphates, which in turn largely oxidize to sulphates; these cannot rise above a small proportion on account of the slight solubility of calcium sulphate." All of these three reac-

³'The Cyanide Process', p. 125.

tions are based on the formation of soluble sulphides, the prevention of which they are supposed to explain.

Clennell⁴ suggests that lead salts may act as an aid in the attack of cyanide solutions on silver according to the following equation:

Silver sulphide is soluble in cyanide solutions without the assistance of lead salts, but the action is much more rapid in the presence of either lead or mercury compounds, and is accompanied by the replacement of the silver by lead or mercury respectively.

Artificial silver sulphide, agitated for 20 hours with cyanide solution containing an excess of lead and mercury, dissolved much more rapidly than when these salts were absent.

The solutions assayed, at the end of agitation, as follows:

	Gm. per ton of solution
Cyanide solution alone	92
With lead acetate	192
With mercuric bichloride	183

THE ACTION OF INSOLUBLE SULPHIDES. The part played by natural sulphides in the precipitation of metals from their solutions has long been known and has been carefully investigated in relation to the formation of ore deposits and especially in the study of secondary enrichment.

Ernest Schuermann⁵ published the results of a series of experiments on the action of insoluble sulphides on solutions of other metals with the following conclusions:

"Many insoluble sulphides, freshly precipitated, transposed the solutions of other metallic salts. In some instances the action is quite rapid at ordinary temperatures, in others long continued heating (several hours) at 100° is necessary. PdS [palladium sulphide] is formed by action of PdCl₂ with sulphides of all the metals following in the series named below, but PdS is not transposed by solutions of the metals following. Silver salts form Ag₂S with sulphides of the metals following in the series, but not with sulphides of Pd, Hg, etc.: Pd, Hg, Ag, Cu, Bi, Cd, Sb, Sn, Pb, Zn, Ni, Co, Fe, As, Ti, and Mn."

Schuermann's investigations covered only the action of artificial sulphides in sulphate, chloride, and nitrate solutions, and it is at once apparent that if this order were the same in cyanide solutions, lead sulphide could be a precipitant of silver. It seemed probable that by determining the effect of artificial sulphides on silver-cyanide solutions, both with and without the presence of lead, some information might be obtained concerning the effect of lead salts in cyanidation. No attempt has been made to determine the position of the different metals in series further than to show the effect of the various sulphides on the silver in solution.

*Both KCN and K₂S present in solution at end of agitation, both were absent in all the other tests.

†Lead acetate used.

Table I shows the results of these experiments which were made with solutions of different alkalinity, as it was early determined that the amount of lime in the solutions caused a great variation in the results. The effect of these sulphides is shown graphically in Fig. 1 and 2. The first of these shows the percentage of silver precipitated in solutions of low alkalinity, which I tried to keep below 0.02% CaO, but which was as high as 0.04% in the tests with antimony, nickel, and iron. Fig. 2 shows the percentage of precipitation in solutions of higher alkalinity, that is, varying from 0.08 to 0.13% CaO. The solution used was made up by dissolving AgCN₂ in sodium-cyanide solution, and contained no other substances than those mentioned in the table. The absence of soluble sulphides was proved before any of the sulphides were used. Different results may be ob-

⁴'Cyanide Handbook', p. 118.

⁵'Über die Verwandtschaft der Schwermetalle zum Schwefel', Liebig's 'Annalen 1888', pp. 249, 326.

tained by varying the amount of sulphide used, the quantity of silver or lead precipitated increasing as the amount of sulphide increases. Different results may be obtained by varying the length of the agitation-period and the quantity of air used. Compressed air was used in agitating the charges, the result being much stronger oxidation than ordinarily would be effected in practice. This probably accounts for the absence of sulphocyanates

FIG. 1. EFFECT OF ARTIFICIAL SULPHIDES ON SILVER CYANIDE SOLUTIONS; KCN 0.013%, CaO 0.020%

in any of these tests, since sulphocyanates were invariably found when the same sulphides were in contact with the same solution without agitation. The effect of time on the amount of silver precipitated is marked; in some instances 85% is precipitated immediately by As_2S_3 , 71% of which is re-dissolved at the end of eight hours agitation.

No quantitative determinations of the lead precipitated were made, but its presence as sulphide was determined

FIG. 2. EFFECT OF ARTIFICIAL SULPHIDES ON SILVER CYANIDE SOLUTIONS; KCN 0.130%, CaO 0.100%

qualitatively nearly always, although a large part of it was converted into the sulphate. FeS and MnS were almost completely changed to MnO_2 and Fe_2O_3 . The action of lead acetate in the solutions containing antimony and arsenic is rather puzzling. While it hinders the precipitation of silver, this does not seem to be caused by the preferential precipitation of lead, at least to the extent shown by the other sulphides. Very little silver can be detected in the precipitate and both As_2S_3 and Sb_2S_3 retain their characteristic color throughout the agitation,

whereas in the absence of lead acetate, they are immediately blackened by the silver sulphide precipitated. In the experiments with these sulphides it would seem that the presence of lead in the solutions tends to keep the silver in solution without entering into the reaction, although further investigation may show that lead is precipitated in sufficient quantity to retard the precipitation of silver. In practice lead salts have produced erratic results when used in the treatment of ores containing arsenic and antimony and at times their use has been considered a detriment rather than a benefit.

ZINC IN CYANIDE SOLUTIONS. It is a matter of common experience that extraction is generally lower with working solutions than with fresh solutions, especially where precipitation of zinc is used, and in some instances the effect of zinc on the extraction has been so deleterious that other methods of precipitation have had to be em-

*Lead acetate used.

It was found impossible to obtain satisfactory extraction on zinc at Nipissing and elsewhere; this led to the adoption of precipitation on aluminum. E. M. Hamilton, in writing of the so-called fouling of solutions, refers to this action of zinc: "The zinc derived from precipitation seems not to effect extraction to any appreciable extent in the majority of instances, but there are cases, especially when treating ores containing antimony and arsenic,

where the presence of zinc lowers the extraction of the silver as much as 10% and in a less degree that of gold. When zinc in solution is found to have this effect, lead in solution will often act similarly, and the addition of lead salts may have to be avoided. The writer has, however, recently come across several instances where the presence of zinc from zinc precipitation was distinctly detrimental to silver extraction, though the addition of litharge was beneficial." The presence of copper in the solution has the same detrimental effect on extraction, according to some observers,⁸ whereas many others have denied it. The action is probably the same, that is, the precipitation of CuS by some of the natural sulphides in the ore, the CuS precipitated being a more active precipitant of silver than the natural sulphides. This precipitation of CuS has not been proved experimentally, and in view of the fact that H₂S is not a precipitant of copper in cyanide solution, the above may not be a true explanation of the action of copper in cyanide solution, although there is no question in regard to zinc.

It has been generally understood that zinc plays the rôle popularly assigned to lead, namely, that of removing soluble sulphides from the solution; but freshly precipitated zinc sulphide is anything but harmless in a silver-bearing cyanide solution unless lead is present in some form, and in solutions of low alkalinity is an active precipitant of silver. Of course if it is not in excess it acts like the soluble sulphides, retarding the solution of silver until the silver sulphide has been decomposed by the cyanide solution and the sulphur molecule removed either by oxidation or combination with the cyanide. The following tests show that much of the silver precipitated by zinc sulphide can be recovered by further treatment.

0.5 gm. ZnS used.

1000 cc. solution containing 128 gm. of silver per ton.

24 hr. agitation.

	KCN in solution %	CaO %	Silver precipitated, %
(1)	0.08	0.130	24.2
(2)	0.08	0.040	89.0

These solutions were strengthened by the addition of cyanide and lime to 0.30% KCN and 0.130% CaO, and agitated for 16 hours more, at the end of which time they assayed 116 and 87 gm. of silver respectively.

The failure of solution containing zinc to give the same extraction as fresh solution would seem to be due to the action of insoluble sulphides in precipitating zinc sulphides, these natural sulphides being inert toward silver.

NATURAL SULPHIDES. Owing to the difficulty of securing suitable natural sulphides for experimental purposes, no work has been done along this line. It would not be reasonable to expect as marked effects from natural sulphides as from the artificial forms, but it has been proved that they do have this effect in their sulphate, chloride, and nitrate solutions.

A long series of tests given in the article referred to showed that sphalerite will precipitate lead, silver, and

copper from these solutions. A sample of ore from the Prieta mine, at Parral, Mexico, containing 6% zinc, 4% lead, and 350 gm. silver per ton in a solution of low alkalinity precipitated over 50% of the silver from a solution carrying 200 gm. of silver per ton. Further tests with the same ore gave the following results:

25 gm. ore used.

250 cc. solution containing 98.5 gm. per ton.

24 hr. agitation.

	Cyanide solution KCN, % CaO, %		Silver in solution at end of agi- tation, gm.	Silver pre- cipitated, %
(1)	0.13	0.08	87	11.6
(2)*	0.13	0.08	98.5	0
(3)*	0.13	0.04	98.5	0

*Lead acetate added.

By using fresh cyanide solution and an excess of lead acetate an extraction of over 40% of the silver could be obtained from this ore. It is probable that most sulphides have some ability to precipitate silver from cyanide solutions, especially after a certain concentration in silver is reached. This would explain why an increased extraction is generally obtained by a change of solutions or even by the dilution of the solution in use.

CONCLUSIONS. Lead salts apparently have three distinct functions in the cyanidation of silver ores.

(1) By aiding in the dissolving of silver through the replacement of the silver atom in silver sulphide by lead.

(2) By being precipitated by various sulphides in preference to silver; the lead sulphide is inert toward silver. It is doubtful if lead sulphide is always inert, as lead sulphide in contact with silver-cyanide solution without agitation will produce some precipitation.

(3) By being precipitated by some sulphides in preference to zinc, which sulphide is an active precipitant of silver.

Since comparatively small amounts of lead salts are required it is probable that their action is similar to sulphide filming as practised in flotation except that in cyanidation the filming is done by the precipitation of PbS and not by the combination of sulphur with the mineral.

Evidently there are two opposing forces operating at the same time, namely, the ability of a cyanide solution to dissolve silver sulphide and the tendency of various sulphides to precipitate silver from a cyanide solution. These two forces are well shown by the action of cyanide on the Prieta ore mentioned above, while 40 to 50% of the silver in this ore can be dissolved by cyanide, if it be treated with cyanide solution containing silver in appreciable quantity, more silver is precipitated than is dissolved.

It has often been asserted that lead salts serve to reduce the consumption of cyanide by combining with part or all of the sulphur that otherwise would form sulphocyanates at the expense of the cyanide. While they undoubtedly do lessen the consumption of cyanide to an extent, it is apparent that this is only done at an economic loss on account of the greater amount of lead salts used.

⁸Julian and Smart, 'Cyaniding Gold and Silver Ores', p. 113.

Lead acetate, $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_3 \cdot 3\text{H}_2\text{O}$, has a molecular weight of 379 as compared with 49 for NaCN, and 7.7 lb. is required to combine with the same amount of sulphur as would be required by one pound of NaCN. If the cheaper PbO is used, 4.5 lb. is required as compared with one pound of NaCN, in either case costing more than the cyanide required to form sulphocyanate.

Some operators prefer litharge to lead acetate; it may be that the preference springs from the practice of adding litharge at an earlier stage in the treatment than is customary with lead acetate. To secure results from litharge, it must be ground in intimate contact with the ore and is therefore generally added in the tube-mill, while lead acetate is more often added during agitation. It seems logical to have small amounts of lead salts present during the entire treatment and especially from the first contact of the solution with the ore, as its addition later on serves principally to aid in dissolving silver that has already been precipitated at an earlier stage.

It was noted by Julian and Smart⁷ that minerals taken from different localities vary greatly in the way they are affected by cyanide solutions, and the sulphides from different mines will probably react differently with the silver in solution also. A careful separation of the various sulphides in an ore, and observation of their action on silver cyanide solutions, both with and without lead salts, should be of much importance in determining the best method of treatment.

Heap-Leaching of Copper Ore at Bisbee

Joseph Irving Jr. recently read a paper before the Bisbee chapter of the American Association of Engineers in which he described the method that will be used by the Copper Queen Branch of the Phelps Dodge Corporation in leaching the ore being mined by steam-shovel methods at Sacramento Hill. The following is quoted from his paper:

In order to prove out sundry smaller experiments a 10,000-ton heap was built at the foot of Sacramento hill and leached continuously for three years and three months. An average of all the samples showed that an extraction of 73% had been made in this time, which compared favorably with the estimated 80% extraction in five years.

One side of the heap, where proper oxidation had taken place, showed extraction of 90% in three years. In laying out this heap no attempt was made to crush the ore, the larger pieces, which naturally rolled to the bottom as the heap was being built, were used to build culverts and drains, and this brought them closer to the oxidizing influence of the atmosphere. This caused them to yield their copper about as fast as the smaller pieces near the top.

The method used was the simple ferric-sulphate process, that is, the solution from the precipitating plant was pumped to the top of the heap and allowed to percolate downward through the heap, being enriched in

copper during its course and being drained from the bottom into the precipitating plant, where its copper content was recovered by precipitating on scrap-iron. The cycle was then repeated.

This was the first successful attempt at heap-leaching in the United States. A number of important innovations have been developed that will greatly shorten the period of treatment of low-grade ores by this method. It has been pointed out that the main defect of this method is the long period of treatment required, which is quite true, but when it is considered that leaching operations can be started as soon as a few tons of ore has been mined and laid out, and that there is no initial expense for crushing and leaching-plant, and that the extraction in the first year is nearly always about half of what it will be in five years, the advantages soon outweigh the one main disadvantage.

At Don Luis the first of the new large heaps is being laid out, 3,000,000 tons of ore, with an area of 2000 by 750 ft., and a depth averaging from 9 to 52 ft. An interesting feature of the Bisbee scheme is the new precipitating plant, which will be the first 'iron' precipitating plant in which all the operations will be done mechanically instead of by hand labor. The solution will flow by gravity through 12 Dorr precipitating-tanks; it will then be pumped back to the top of the heap. The copper precipitated will be washed free of the iron by agitating in the tank for a short period, after which the copper precipitated will be allowed to settle in the bottom of the tank. The Dorr mechanism in the tank is then lowered and rotated slowly, the discharge plug in the centre of the bottom of the tank opened, and the copper precipitate discharged. The precipitate goes to a Dorr classifier, where the coarse copper is separated from the fine. The coarse copper is deposited on a drying-floor to dry before shipment, and the fine goes to a Dorr thickener, the overflow solution from which is returned to the precipitating-tanks, while the thickened solution is discharged through Dorr pumps to the various sections of the drying-floor. The iron necessary for the operation of the plant is unloaded from the railroad-cars and loaded into the precipitating-tanks by a five-ton gantry crane.

Two men will operate the plant, where a plant of the ordinary kind would require at least ten or twelve men. All the dirty and unpleasant work will be eliminated.

THE most notable new mining development of the year in Idaho was in the phosphate fields in the south-eastern corner of the State, according to Robert N. Bell. This interesting field of the most essential agricultural fertilizer mineral, has been the subject of elaborate study in recent years by the officials of the U. S. Geological Survey. This study resulted in the publication of a number of well illustrated bulletins and recently the preparation of a professional paper now nearing completion, by George R. Mansfield, who estimates a mineable resource, in this limited area of the great western phosphate field, to be 5,000,000,000 tons of 70% tri-calcium phosphate.

Karl Eilers v. Guggenheims

Office of American Smelting and Refining Company,
120 Broadway.

New York, January 20, 1921.

Dear Sir:

There is enclosed herewith the regular notice of annual meeting of stockholders.

There is also enclosed, as heretofore, the customary form of proxy, which you are requested to sign and return in the accompanying envelope, if you cannot be present at the meeting in person.

In former years, it has never been necessary to add anything to the simple request for proxies as made above. It should be, and doubtless is, unnecessary to say anything now. Since, however, those who have been charged with the management of the Company for years past, to the present time, have very recently been attacked by one of the Company's discharged employees, who is seeking proxies for himself, it is proper that a statement should be made in fairness both to the directors and to the stockholders of the Company. Such a statement is accordingly appended.

I desire to add (in reference to the criticism made of my stock holdings) that my wife and myself own stock in the Company of the par value of over \$2,800,000, and bonds to the extent of \$300,000—a total of over \$3,000,000.

Respectfully,

SIMON GUGGENHEIM,
President.

STATEMENT ON BEHALF OF THE DIRECTORS OF THE AMERICAN SMELTING AND REFINING COMPANY

The undersigned directors of the American Smelting and Refining Company desire to make a statement to the stockholders of the pertinent facts with regard to the matters involved in the attack recently made upon the present management of the Company.

The attack is made by Mr. Karl Eilers, who is asking proxies for himself and a single associate, which will give them power to elect the entire Board of Directors. IN EFFECT, THE REQUEST IS FOR A BLANKET AUTHORIZATION TO MR. EILERS TO CREATE AN ENTIRELY NEW ORGANIZATION, SUBJECT TO HIS SOLE DOMINATION.

Mr. Eilers was for many years a director, and first became a Vice-President in November, 1916. After much friction, it became manifest that, for the welfare of the Company, his association in its management would have to be terminated. He was accordingly removed from office and dropped from the directorate at the annual election of last year. It is perhaps natural that this action should have aroused bitterness and resentment on his part, and that his anger should be principally directed against President Guggenheim and his brothers. The feeling thus engendered is sufficient to account for

his present attitude and for the recklessness of his statements.

In December last, Mr. Eilers started his campaign for stockholders' votes by bringing a wholly unnecessary and unjustifiable suit against the Company for a writ of mandamus to permit him to examine the stock books and take off the names and addresses of the stockholders and the number of shares held by each, alleging that such permission had been refused, when in fact he had been freely given access to the books and had spent days in examining them through a representative before the suit was brought. While the Court promptly denied the writ and dismissed the petition, after the matter was heard, the apparent object was accomplished, namely, wide newspaper publicity to the various charges of misconduct or mismanagement which he had injected into his petition. These charges he could not be called upon to prove in the application heard by the Court, and they could only be met by a denial and answer on the part of the Company setting forth the facts.

A pamphlet giving the entire Court proceeding has been sent to all stockholders, a careful reading of which is again suggested.

If you will analyze the statements or charges made, in the light of the surrounding circumstances and of the facts set forth in the answering affidavit of Mr. Newhouse, Chairman of the Board, contained in the pamphlet mentioned, you will have no difficulty in perceiving how essentially groundless and unsubstantial and inherently improbable they are. For the most part, they turn on mere matters of opinion, and in this respect they mean no more than that Mr. Eilers sets his individual opinion against the opinion of the twenty odd men constituting the Company's Board of Directors. While Mr. Eilers now inveighs against the alleged undue and baneful influence of the "Guggenheims", it is to be noted that throughout the long period of his service with the Company, the stockholders or the public never heard a word of criticism from him, and that it was not until after his connection with the management had ceased, in fact not until he began his campaign for proxies, that his complaints were made.

Referring to the several accusations in detail:

(1) The suggestion or intimation (it is not definitely charged) that the Messrs. Guggenheim, or some of them, have been overpaid by the Company or have received large salaries is utterly without foundation. Aside from the President, no member of the Guggenheim family now receives any salary whatever, or has received a salary since January, 1919. The salary received by the President is less by \$10,000 than Mr. Eilers enjoyed at the time of his discharge. The salaries paid in former years to such of the Messrs. Guggenheim as held office in the Company were always less than salaries paid at the same time to other officers. Such salaries as they did receive

were reduced on their own motion in times of financial stringency. The Messrs. Guggenheim never participated in any of the bonuses paid to all other employees and officers, including Mr. Eilers.

(2) The charges that the Messrs. Guggenheim have sought to manage the Company, in disregard of the interests of the stockholders, in order to serve other and adverse interests, and have promoted enterprises which should have been developed for the Company's account, are embodied in three specifications. As these charges are specific, it is a simple matter to refute them absolutely.

(a) The falsity of the charge that the Company was not permitted to acquire a certain Bolivian tin property examined by it because it was wanted by Guggenheim Brothers, who did acquire it, is shown by the simple fact that no tin or other property ever considered or examined by the Company has been acquired by the Guggenheims.

(b) With reference to the Premier Gold Mining Property: So far from the Company having been forced to give up to Guggenheim Brothers one-half of its option on a quarter interest in the property, the Company solicited the firm named to take a half of its option off its hands, for the reason that, while it was willing to take a chance on a one-eighth interest, it wanted for financial reasons to limit its investment and its risk to that amount. No developments thus far have caused us to question the wisdom of the action taken.

(c) It is charged that the Messrs. Guggenheim promoted mining properties not for the Company's account but for their own benefit. When such enterprises were undertaken, the outcome was problematical in the extreme, the capital required was very large, and the risks of loss were very great. Neither this Company, nor any other company, unless specially formed for a distinctly speculative venture, would have thought of risking its resources, credit, and the property of its shareholders, in such distant and hazardous enterprises. It is doubtful if any one but Mr. Eilers could think otherwise. The responsible officials of the Company never even contemplated such action. They would have been truly unworthy of their trust had they done so. This Company is distinctly of the class enjoying what is practically a steady manufacturing business. It is not a speculative promoting company. On the other hand, the eventually successful development of the properties by the Messrs. Guggenheim and their associates has greatly benefited this Company through the valuable new smelting and refining business which thus came to it.

(3) The charges which have to do with the marketing of copper (the word "gambling" is used) are incorrect, misleading and grossly unjust. The essential facts are stated by Mr. Newhouse in the pamphlet mentioned, to which you are again referred for an account of what was actually done. What Mr. Eilers says on the subject is an illustration of the inconsistencies into which he is led in his desire to convict the management of some wrongdoing. In his petition, he complains loudly of alleged

losses resulting from a course of action compelled by the existence of certain selling contracts, while in his latest statement he complains, just as loudly, of alleged losses resulting from the termination of those contracts, although such termination will permit the Company to follow a selling policy which he advocated in his earlier statement, and which it could not otherwise pursue.

Any losses in marketing copper were not due to any change of policy, but were the inevitable outcome of the Sales Agency arrangement under the abnormal and unexpected conditions created by the war. The basic vice of the Sales Agency as developed by war conditions was the pro-rata feature, under which this Company could only sell its copper in the same proportion that the Mining Companies sold their copper. This feature the Mining Companies, though repeatedly urged by this Company, would never consent to forego. In justice to the Mining Companies, their right to this provision could not be questioned; in justice to the Smelting Company, the effect of that provision could only be avoided by the termination of the Agency.

At the start of the Agency, the Mining Companies (Utah, Ray, Chino, Nevada Consolidated, and much later Braden, Kennecott, Cerro de Pasco, and Chile) were all new and small mines, and the amount of copper belonging to this Company constituted a large percentage of the total copper in the Agency. The Mining Companies in the Agency have since become among the largest producers in the world, and by the time the war broke out, the proportion of the copper in the Agency owned by this Company (notwithstanding it had also increased) was only about one-fifth of the total amount available for sale. The Smelting Company was under contract obligation to sell to the best advantage. Obviously, the opinion of the owners of four-fifths of the copper should control the policy of selling, or the Smelting Company might be the subject of a heavy claim for damage.

The Mining Companies, having only the cost of production, wished to withhold from sale on a dull market, and to sell largely when the price met their opinion of the future.

The Smelting Company sought, not to make a profit in the buying and selling of copper, but to make its profit out of smelting and refining, and was anxious to sell its copper at the price it paid for it in the ore.

Gradually, the Mining Companies came to think that the Smelting Company's interest in selling its own copper might unfavorably affect the Smelting Company's attitude in seeking to get the best price.

On the other hand, the Smelting Company felt that it was often unable to sell its own copper, because the Mining Companies took a different view of the future of the market, and also often because in dull periods the market would not consume the total amount of copper controlled by the Agency.

As the result of this duality of interest, it became necessary to terminate the Agency. As a matter of fact, of their own motion, some of the most important members of the Agency themselves took the initiative and with-

drew because of a conviction that the conflict of interest above described could not be avoided. The decision to terminate the Agency, as to the remaining members, was reached by the entire Board (excluding the Guggenheims) after most careful and prolonged study and investigation.

The undersigned wish to emphasize that every member of the Guggenheim family studiously avoided influencing the opinion of the remaining directors, refrained from the expression of any opinion, and absented themselves from the meeting at which the question was decided, in order that no charge of a conflict of interest on their part could possibly be made.

CONCLUSION.

It is worthy of note that even Mr. Eilers does not question the fundamental soundness of the Company's position, the assured permanency of its business, its industrial and commercial stability, its enviable credit, and its assured earning power under normal conditions. This Company, like virtually every other company the country over, is going through a period of great industrial and commercial depression, involving lower earnings, large cash absorption, and reduced operations. It would be absurd to hold the management of the Company responsible for this condition of affairs. Yet this time is chosen to make a wholly unwarranted attack, which has unnecessarily depressed the market value of the Company's securities. There is nothing in the present situation differing in principle from similar periods of depression and financial stringency, notably those of 1907 and at the outbreak of the war in 1914. In each of these cases, the metal industry was among the first to revive. There is every reason to believe that a similarly early revival will follow from the present depression; such is the confident belief of the management.

The management of this Company has been faithful to the interests of its shareholders; it has served no other interests; its record has been free from any taint of dishonest or selfish exploitation; it has earned the confidence of stockholders, not only because of its clean record, but by reason of results accomplished. As to the influence of the Messrs Guggenheim and the value of their services, the outstanding fact is that their association with the Company has been coincident with the great growth and signal success of the corporate enterprise. The undersigned, for themselves and for their fellow directors, desire to record their belief and conviction that the part taken by the Messrs. Guggenheim in the management of the Company and its affairs, has been the greatest single factor contributing to the Company's growth and prosperity, and that it would be most unfortunate if the Company should now be deprived of the benefit of the extraordinary commercial and financial vision and ability they possess.

Electricity in Coal Mines

During the three decades, 1890-1920, electricity as applied to coal mining made rapid progress until today there remains hardly a task or an operation connected with coal mining that is not directly or indirectly concerned with the use of electricity. From the time the miner takes his electric cap-lamp in the morning until he has completed his task at night he is continually using electricity or electrical equipment. The electric signal tells the hoisting engineer when to start and to stop the hoisting engine. The lights at the several levels and at dangerous crossings throughout the mine are usually electric. The telephone is a part of the equipment necessary underground. Electric shot-firing and electric shot-firing systems are becoming widely used. Electric pumps handle much of the water in the mines. The haulage of coal is done largely by electric-trolley and by storage-battery locomotives and electrically operated hoists. Each year some new electrical device is introduced, says a recent publication of the Bureau of Mines. Electrical equipment for mines, in order to be safe and efficient, must be properly designed, carefully installed, inspected at regular intervals by competent men, and maintained in good working condition. In general, the best way to obtain satisfactory electrical equipment for mine service and to ensure its proper installation, inspection, and maintenance, is for each State to make and enforce fundamental rules and regulations relating to the use of electricity and electrical equipment in and about coal mines. The rapidity with which electrical equipment has entered into the many phases of coal mining has exceeded greatly the advance of regulations governing its use. Even the best electrical mining codes in force need modernizing, and some States have even neglected to mention the use of electricity in their mining laws.

IRON ORE mined in 1920, exclusive of that which contained more than 5.5% of manganese, is estimated at 67,773,000 tons, an increase of 12% as compared with the output in 1919, according to the estimate of the U. S. Geological Survey.

Radio-Activity and Some Practical Applications

By C. W. Davis

***INTRODUCTION.** In this survey I shall discuss briefly the following subjects:

1. The discovery of radio-activity and of radium.
2. The disintegration of radio-active elements.
3. The production of radium and mesothorium.
4. The properties of Becquerel rays.
5. The detection and estimation of radium.
6. Radium and mesothorium in self-luminous compounds.
7. The therapeutic application of radium and radium emanation.

THE DISCOVERY OF RADIO-ACTIVITY. In 1895 W. C. Röntgen found that X rays excited fluorescence on screens coated with barium platino-cyanide or calcium tungstate and that these rays fogged photographic plates. The next year H. Becquerel, knowing that X rays caused fluorescent substances to glow, wondered whether the converse were true, that is, would phosphorescent bodies give off invisible penetrative rays. To investigate this, he placed phosphorescent substances on a photographic plate that had been wrapped in two sheets of thick black paper. In about 24 hours, when the plate was developed, a silhouette appeared on that part of the plate which had been directly under a piece of phosphorescent uranium salt. Becquerel attributed this action to rays emitted by uranium and found that these rays had the property of causing a charged electroscope to discharge. A substance emitting these rays, now known as Becquerel rays, is said to be radio-active and to have the property of radio-activity.

In 1898 Professor and Madame Curie found that certain uranium ores were much more radio-active than pure uranium salts. From this they concluded that some element was present in the ore, other than uranium, which caused the radio-activity. They succeeded in extracting radium in the form of the chloride and showed that it was over one million times more active than uranium.

THE DISINTEGRATION OF RADIO-ACTIVE ELEMENTS. According to Rutherford and Soddy, the atom of a radio-active element undergoes spontaneous disintegration, forming a series of radio-active substances quite different from the parent element in chemical properties. This phenomenon within the atom is not affected by any chemical or physical agencies that have yet been applied from without. Thus the uranium atom, uranium having an atomic weight of 238, expels an alpha ray with the formation of a new element, uranium X₁, the latter hav-

ing an atomic weight of 234. The difference of four in the atomic weights of the two elements is due to the loss of a helium atom, helium atoms consisting of alpha particles, each of the latter being composed of four positive and two negative units of electricity. Uranium X₁ emits a beta ray and forms uranium X₂, which in turn breaks down, a series of elements being formed by such processes.

The half-value period or half-period of these elements (by that is understood the time required for one-half the original amount of any radio element to disappear) is very different, ranging from about five billion years in the case of uranium to the fractional part of a second in the case of radium C₁. In spite of the slow rate of disintegration of some of the radio elements, old unaltered minerals have reached equilibrium, that is, the radio elements have a fixed ratio with one another. This fact makes possible the usual case in which one element can be used for the determination of another, as will be shown later.

Just as uranium is the parent of a series of radio-active elements, thorium and actinium each act in a like capacity for a different series of radio-active elements.

THE PRODUCTION OF RADIUM AND MESOTHORIUM. Salts of radium, in the uranium series, and of mesothorium, in the thorium series, are now produced on a commercial scale. Radium in the form of chloride or bromide is obtained from uranium ores by chemical processes that differ in their earlier stages. In most cases the final purification or concentration depends upon fractional crystallization of mixed chlorides or bromides of radium and barium. Barium, having much the same properties as radium, is always found with it at the crystallization stage. Since about two tons of ore (the quantity, of course, varying with the grade of ore used) must be treated to obtain a salt containing 10 milligrammes of radium element (that is, about one three-thousandth of an ounce), the care that must be used in such a process may be appreciated. When the demand for radio-active material for the preparation of the self-luminous compounds used on instrument dials became considerable, a process was evolved in which mesothorium was recovered as a by-product when monazite sand was treated to recover thorium and cerium for use in the manufacture of gas-mantles.

THE PROPERTIES OF BECQUEREL RAYS. A statement of the properties of the primary rays emitted by radio-active substances, that is, the alpha, beta, and gamma rays, will indicate what practical use can be made of them.

Alpha rays are positively charged particles projected at

*Read before the University of Nevada Chapter of the American Association of Engineers, November 3, 1920, at Reno, Nevada, and published by permission of the Director of the U. S. Bureau of Mines.

about one-fifteenth the velocity of light, the velocity and range depending upon the source. Helium atoms have been said to be identical with alpha particles, each of the latter, as previously explained, consisting of four positive and two negative units of electricity. (Helium, as will be remembered, is one of the rare inert gases, traces of which are found in the atmosphere and which has been discovered recently in considerable quantities in some natural gases, and is used to fill balloons when a non-explosive gas is required.) The high velocity and appreciable mass of the alpha particles give them an enormous kinetic energy, which, when the particles are stopped, produces heat, one gramme of radium supplying 134 calories of heat per hour, 124 calories of which are due to the alpha rays. This heat is equivalent to that obtained by burning 400,000 grammes of carbon. H. H. Barker, in a paper read before the Teknik Club of Denver, used an interesting illustration to show the enormous energy content of radium. He said, "One ounce of radium in its complete transformation to the end-products will give off enough energy to lift five million tons through a distance of 30 ft. In other words, one ounce of radium will give off enough energy to lift 100 of the largest battleships afloat entirely out of the water". This does not mean that the energy could be used practically, for even if the cost were not prohibitive, the slow rate at which this energy is emitted cannot be influenced. Consequently, the available energy at any time is comparatively insignificant. The penetrating power of the alpha ray, however, is exceedingly small, being absorbed by a sheet of writing paper, a piece of thin glass, or even coatings of varnish. The maximum range of the alpha rays in air at standard pressure and ordinary temperature is about seven centimetres, the air being ionized by the passage of the particles and becoming a conductor. For this reason a charged electroscope is discharged in the presence of substances giving off these rays. The alpha rays affect photographic plates and also cause phosphorescent substances, such as barium platino-cyanide, calcium tungstate, zinc sulphide, willemite, etc., to glow in the absence of light. The alpha rays are deflected in a powerful electric or magnetic field.

Beta rays consist of negatively charged corpuscles or electrons expelled at velocities approaching that of light. Their small mass, about one seventeen-hundredth that of the hydrogen atom, and high velocity produce a penetrating power one hundred times greater than that of the alpha rays, thin glass having very little effect on them and two or three millimetres of lead being required for their complete absorption. The ionization effect of the beta rays is only about one-hundredth that of the alpha rays, but their deflection by an electric or magnetic field is greater than, and in an opposite direction to, that in the case of the alpha rays. Beta rays are less effective in producing phosphorescence in minerals than are alpha rays.

Gamma rays, unlike the alpha and beta rays, are not corpuscular in nature, but, like light rays or X rays, consist of electro-magnetic disturbances. The wave-length

of the gamma ray is much less than that of the X ray and the penetrating power, being from ten to one hundred times greater than that of the beta ray, is also much greater than that of any X rays, penetrating the human body or passing through a foot of iron.

The ionizing effect is only about one ten-thousandth that of the alpha rays and the power of producing phosphorescence in minerals is much less than that of the alpha or beta rays. The gamma rays are not deflected by a magnetic field.

THE DETECTION AND ESTIMATION OF RADIUM. Radium ores usually are purchased on their uranium content, that is, the ore is analyzed for uranium, this value being then divided by a constant to give the quantity of radium in the ore. This is possible, as was stated before, because radium and uranium in an ore have a constant ratio, which has been found to be about 3.33 times 10^{-7} . This ratio is always found to hold when large samples are taken. Small samples often show abnormal ratios, probably due to transposition of radium within the ore deposit. Although this indirect method is usually employed for the estimation of radium in ores, the radio-active property of the radio elements is always used when an exact knowledge of the radium content in a substance is desired. A radio-active method is also used for the detection or rough estimation of radium in ores.

The spectroscope has detected very small quantities of an element, the neon in one-twentieth of a cubic centimetre of air having been identified. Since only one one-hundred-thousandth part of the air consists of neon, then the quantity of neon detected would occupy only one two-millionth of a cubic centimetre at standard pressure and temperature. The detection of alpha rays, however, has been shown to be over one million million times more sensitive than this spectroscopic result.

The electroscope as used for the detection and approximate estimation of radio-active material in ores consists essentially of one chamber in which an aluminum-foil leaf is suspended in such a way as to be entirely insulated from the chamber but connected to a conductor suspended in a second chamber directly below the first, the conductor being insulated from its chamber. The lower chamber has a hinged door for the introduction of samples. The upper chamber is equipped with wire, insulated from it, which may be brought in contact with the leaf system and through which a charge may be introduced to the leaf with a rubbed ebonite rod. The upper chamber is also equipped with a telescope containing a graduated scale by means of which the movement of the leaf can be observed. The leaf system is protected from outside influences by means of a wire net at points that are left open for the introduction of light, etc.

The rate of fall of the charged leaf, in divisions per second, with no radio-active material in the ionization chamber, is called the natural leak. This should be very low for satisfactory results. The ore to be examined should be ground to a coarse sand and spread evenly over a definite area of a container, which is then placed in the ionization chamber of the electroscope. The rate of fall

of the leaf is then noted, and if the leaf moves faster than the natural leak of the instrument, the presence of radio-active material is indicated. If an approximate measure of the uranium content of the ore is desired, an analyzed sample of ore similar to the one being tested is ground to the same fineness as the unknown, spread over the same area, placed in the ionization chamber, and the rate of fall of the leaf noted. The natural leak is subtracted from the observed rates of fall of the two samples. The corrected rates of fall are to each other as their uranium content; one being known, the other is easily determined. Numerous precautions must be observed to ensure trustworthy results. The illumination must be constant. The atmosphere must be reasonably dry. The readings should be taken over the same points on the scale. The physical condition of the samples should be nearly identical. Although this method, known as the alpha-ray method, is not exact, it is useful in the detection of radio-active materials, especially in the field.

As explained before, although the gamma rays have a comparatively low ionizing power, they are not affected appreciably by a sheet of metal that completely absorbs the alpha and beta rays. This forms the basis for the gamma-ray measurement of radium, which is the most accurate method for determining radium in salts containing over 0.1 milligramme of radium. It compares the rate of electroscopic discharge of an unknown salt with that of a standard salt, using identical conditions of measurement, the rate of discharge being proportional to the quantities of radium in the samples.

A special form of electroscope is usually used, but any alpha-ray instrument may be used by placing a lead screen about one-fourth inch thick between the electroscope and the samples being examined. These samples must be placed in exactly the same position with respect to the electroscope and should be sealed in glass tubes of the same thickness, otherwise corrections must be applied. The radium salt must have been sealed for a month or more to allow its disintegration products to come into equilibrium with it before comparing it with a standard or the time of sealing must be accurately known so that the percentage rate of accumulation of activity may be determined.

For the exact determination of small quantities of radium, its disintegration product is removed and its quantity determined in an emanation electroscope. The emanation electroscope is similar to the alpha-ray instrument, but the lower chamber is made air-tight and fitted with two stop-cocks for the introduction of air or gas. Radium is gradually changing to radium emanation. Radium emanation is the only gaseous member of the radium disintegration series and therefore may be separated readily from the other members.

The emanation is removed from solid substances by heating or fusion while passing air, and from solutions by boiling with the passage of air. The gas is collected in a gas burette of special design over a hot potassium hydroxide solution and then transferred to the emanation chamber of an electroscope through a micro-drying tube.

This is accomplished by partly evacuating the emanation chamber, attaching a tube from the gas burette to one of the stop-cocks and opening the stop-cock. The sample previous to the removal of its emanation must have been sealed up for at least a month or else the results must be corrected to conform to the equilibrium conditions existing at the time of treatment. The electroscope must be standardized, that is, the emanation from a known quantity of radium is placed in the emanation chamber and, after standing three hours to get the maximum ionization effect, the rate of discharge of the leaf is observed. The same procedure, namely, getting the rate of discharge, is carried out on the unknown sample, and after correcting for the natural leak in both cases the rates of discharge are proportional to the radium content of the two samples.

RADIUM AND MESOTHORIUM IN SELF-LUMINOUS COMPOUNDS. Phosphorescence is generally understood as the property of a body to glow in the dark after having been exposed to the action of light. Certain phosphorescent substances are activated by Becquerel rays, the alpha rays being much more effective than the beta rays, which in turn are more effective than the gamma rays. The light effect when caused by radio-active rays has been shown to consist of an infinite number of individual flashes of light and is supposed to be the result of the collision of radio particles with particles of the phosphorescent substances. Various theories have been advanced to account for this action, but, in general, the opinion is held that the phenomenon is part physical and part chemical in nature. Other rays produce a similar effect, but substances that are most highly luminous when activated by one kind of ray may not be nearly so luminous when activated by other rays, that is, each substance has a class of radiation through which its maximum luminosity is attained. For example, two phosphorescent compounds may be exposed to the light, and, when seen in the dark, *A* is more luminous than *B*, but when the same substances are exposed to Becquerel rays, *B* may be the more luminous. After a phosphorescent substance has been exposed to alpha rays for a considerable period, the phosphorescence is gradually destroyed. It is said to 'decay'. The rate at which this decay progresses depends on the intensity of the bombardment by the alpha rays. It has been said that in the presence of large quantities of radium the phosphorescence from phosphorescent zinc sulphide would disappear in 12 hours. As usually prepared the phosphorescence of phosphorescent zinc sulphide will last for several years before becoming too dim for further use.

Barium platino-cyanide under the action of alpha rays turns a brownish color and loses its phosphorescence. The original color and also the phosphorescence may be restored by heating. Phosphorescent sulphides of barium, calcium, and strontium when destroyed by the action of alpha rays may be restored to their original condition by passing a current of hydrogen over them, but not by heating alone. Phosphorescent zinc sulphide, however, its phosphorescence destroyed by alpha-ray bombard-

ment, has only been regenerated by preparing the material anew.

Although the preparation of phosphorescent zinc sulphide for use in the manufacture of self-luminous compounds is a trade secret, each producer carefully guarding his formula and method of procedure, the general features of the process seem to be as follows: A zinc salt is freed from impurities that interfere with the formation of the phosphorescence, such as iron, nickel, tin, etc., and the zinc is then precipitated from solution as a sulphide, a small quantity of some other element is introduced either before the precipitation takes place or later, and the sulphide is dried, ground to pass a 200-mesh screen, placed in a closed crucible, and heated to a bright red for a definite length of time. The quantity of the addition substance is so small, in the finished product, that its identification is difficult. For this reason the secret of the composition of the substance is reasonably safe. Although the amount of this substance is small, it has a very marked influence on the color and intensity of the luminescence produced when the material is acted on by radio-active rays. The finished phosphorescent zinc sulphide is mixed with a very small quantity of a radium salt and is ready for use. Although the quantity of radium employed depends somewhat on the use that is to be made of the compound, a very bright material of comparatively short life having more radium than one not so luminous but of longer life, the limits are about 0.1 to 0.25 mg. per gramme of phosphorescent zinc sulphide. The luminous compound may be mixed with water-white varnish and painted on or enclosed in glass and used for illuminated instrument dials, light-pulls, keyholes, etc. Although radium salts sell for more than \$100,000 per gramme of radium element contained, the quantity of radium required for enough material to illuminate the dial of a watch has been estimated to cost 15 cents.

The use for radium in luminous compounds has been discouraged and for good cause. The radium so used is lost, and since the known deposits of radium ores are being rapidly exhausted, the future supply of radium for use in therapy should be gravely considered and no waste permitted at the present time. Although the half-period of mesothorium is short when compared to that of radium, the rate of decay of phosphorescent zinc sulphide is such that mesothorium can well replace radium in the preparation of self-luminous compounds.

THE THERAPEUTIC APPLICATION OF RADIUM AND ITS EMANATIONS. The use of radium in therapy depends on the fact that intense rays from radio-active substances have the power of destroying living cells; not only that, but there is a differential action in that diseased cells are more readily attacked than healthy ones. Healthy cells, however, are affected if exposed for some time to an intense radio-active source, an exposure of a few minutes causing a severe burn in case of a salt with high radium content. The burn is similar to an ordinary burn except that the results do not appear so rapidly, a blister often developing a day or so after the exposure was made. The alpha rays, having such a small penetration, are of no

therapeutic value, but the beta and gamma rays, especially the latter, find their greatest value in this field. Beta and gamma rays are not emitted by either radium or its next disintegration product, radium emanation, but radium *B* and radium *C* furnish them. Radium *B* and radium *C*, however, have such short half-periods that it is usual to employ either radium salts or radium emanation in which the disintegration products radium *A*, *B*, and *C*, have come to their maximum activity. In the case of radium salts they may be sealed up in glass tubes and used in that condition. Radium emanation is as a rule removed from a solution in which the emanation has been allowed to accumulate. The emanation, having a half-period of 3.35 days, must, of course, be used while it contains the desired activity. The maximum activity is reached in three or four hours after its collection.

In spite of its short half-period radium emanation has several advantages over radium salts in direct application. The emanation is comparatively inexpensive, so that the loss of a tube of it is of no great moment. Radium, on the other hand, is not only very valuable but is not always readily replaced. Emanation can be readily concentrated by removing extraneous gases by chemical means or by condensing it in liquid air and placing it in a container the size of a sewing-needle; or it may be diluted and allowed to fill any form of applicator.

The application of radium or radium emanation in therapy not only requires a specialist but also demands a constant access to considerable quantities of radium, 500 milligrammes not being considered a surplus. A number of factors determine the results obtained by the action of the radio-active rays: the intensity and time of exposure, distribution, distance of the source from the healthy tissues as well as from the lesion, and the nature of the screen between the radio-active material and the patient. All these are of importance.

The use of radio-activity has effected numerous remarkable cures in a large variety of diseases, such as ulcers, malignant skin diseases, tumors, various forms of cancer, and the success to be expected in this direction is directly proportional to the development of a knowledge of technique.

THE quantity and value of important mineral products of the Philippine Islands in 1919 is shown below. It will be observed that gold is by far the most important product and except for silver the only important metal.

Product	Quantity	Value, *pesos
Metallic:		
Iron, metric tons	67	34,964
Iron ore, metric tons.....	18,598	92,990
Silver, fine grammes	261,558	18,828
Gold, fine grammes	1,970,651	2,619,449
Non-metallic:		
Asbestos, metric tons	375	37,500
Bituminous rock, metric tons..	1,400	21,000
Cement, barrels	10,396	124,752
Coal, metric tons	32,892	822,300
Lime, metric tons	20,000	534,000

*Normally equal to 50c. in U. S. currency.

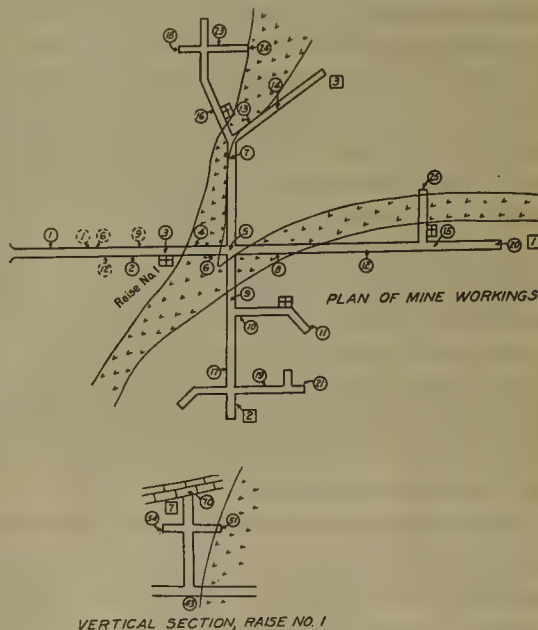

A Method of Recording Geology in Development Work

By C. Erb Wuensch

My observations have revealed an almost universal neglect on the part of operators of small mines to properly record geologic data that are obtained in the course of mine development. Even some of the larger companies, who keep accurate geological maps, may find some of the following suggestions of value. In the development of mines the operator, who is in charge of the work, often fails to realize that some day his successor might profit by a few properly preserved specimens of ore and country rock as well as some notes relative to the ideas he had in mind in conducting his development. Moreover, the effort required in recording this information may prove of value to himself; it will stimulate accuracy, observation, and imagination.

From these general remarks one can readily outline in his mind the method of procedure to accomplish the purposes suggested. It may be of interest for me to give a few suggestions as to some of the methods that I have found effective. In the map room build two sets of shelves or cabinets. One will be used for permanently preserving the various type specimens; this will be the 'permanent cabinet'. The other will be used as a receptacle for the specimens that are collected during the progress of the various workings—the 'temporary cabinet'. It is well to cultivate the habit of carefully collecting specimens, and to compare them underground with the material in the same drift and thus obviate the necessity of gathering innumerable specimens that will serve no useful purpose. However, it is good practice to collect too many rather than too few specimens. Often slight changes in alteration or mineralization may be imperceptible underground, whereas if examined in daylight they may have some important significance. The specimens may be placed in small canvas bags with a metal tag, and sufficient notes taken to identify the specimen, just as you would handle a sample of ore. The positions of these specimens are indicated on the mine maps in pencil† and the specimens placed in the temporary cabinet with the tag to identify it. Periodically the various specimens are compared. Those having certain individual characteristics are labelled and filed in the permanent cabinet. Their positions are indicated with ink, by means of numbers placed within a small circle as indicated in the accompanying sketch. The number should be entered in a note-book. Under the number the name of the rock should be written, its significant characteristics, and any other descriptive notes deemed necessary. The position from which the rock was obtained, should also be included in the descriptive notes so as to have a cross reference to the rock in the event

that one finds a rock or mineral specimen in the type collection which he wishes to compare with another whose position he does not know. He, therefore, has merely to refer to the list of rocks and from the description given he can quickly ascertain its position on the map. Some method of dividing the mine into blocks and referring the numbers to some known origin similar to the co-ordinates X, Y, Z, as used in solid and analytical geometry, might be used to advantage.‡ The other rocks, from which these type specimens were selected, are then discarded. The pencil numbers corresponding to the rejected specimens are erased from the map and the metal tags placed back with the 'active' tags. It is a good idea to have

about 100 metal tags stamped with numbers from one to one hundred. In this way errors in numbering, by duplication, of the temporary rock specimens is obviated.

The permanent type-specimens are numbered consecutively, in the order in which they are placed in the cabinet, regardless of their location. These are numbered with India ink, written on a small patch of white lead, just as specimens are labeled in museums. This makes a reliable means of identification. It is surprising how few specimens it is necessary to collect in order to have a permanent record of the characteristic rocks from a mine. In long drifts, frequently, but one or two specimens are required. Or, if a number of cross-cuts, for instance, all

†The numbers within the dotted circles are intended to illustrate those marked with pencil.

‡'Scientific Numbering of Mine Workings', by C. Erb Wuensch, 'Engineering & Mining Journal', Dec. 2, 1916, page 977.

cut the same formation, it will not be necessary to collect specimens from each individual cross-cut. A number can be given, in reference to each cross-cut that will correspond to the one taken from one of the other cross-cuts.

The numbers in the squares are those which will be used to refer to the note-book in which brief mention is made as to the idea that the operator had in mind at that point in his development. For instance, take the point in square No. 1, at the end of the main tunnel (see sketch). The memorandum referring to this number might mention that at this point drifting was discontinued temporarily on account of the necessity of curtailing the development expense, and that in the future it is intended to advance this drift and cross-cut the dike to the north at regular intervals. Likewise at the point in square No. 7, shown in the vertical section of raise No. 1, the operator would probably say that limestone was struck on top of the raise and that it is inadvisable to extend this raise, as no ore had been found above this horizon. These brief memoranda will enable the later operator to know why a particular piece of work was done, or why further development work was not done.

Anyone who has done geologic mapping realizes how difficult it is to indicate graphically some of the subtler geologic distinctions, such as variations in degree of silicification, texture of the rock, metamorphism, or mineralization in a formation for which he has used a certain legend. It is, therefore, evident that, by the use of properly recorded specimens, a more accurate interpretation of the geology can be conveyed. By the intelligent use of these specimens, in conjunction with geologic maps, one is able to study more intensively the geology of a mine. For instance, by referring to the geologic map, two portions of a mine may have identical structural features; in one there may be ore, whereas at the other there may be none. Yet by comparing the rock specimens from these two regions it may be possible to see immediately the differences in degree of mineralization.

Another advantage of this system of collecting samples is its use at a large mine where there is liable to be a more or less frequent change in personnel. The newcomers will be able to learn rapidly the geology of the mine. Portions of the mine which now may be inaccessible can also be studied. This is important because later developments may reveal the advisability of further prospecting in such areas.

It might be well to call attention to the fact that a man with practically no geological training can utilize these ideas. Even though he does not know the scientific names of rocks or minerals, he nevertheless can distinguish one from the other by direct comparison and may even coin names to meet his demands. If the mine is subsequently examined by an engineer, the latter can translate the practical man's terminology into technical language as well as make the necessary corrections in mapping and geological interpretation. Still another advantage that might be mentioned is the manner in which it facilitates sending reports to consulting engineers, who make their residence in the larger cities and

pay only periodic visits to the mine. It will make the mine reports more intelligible and valuable to them.

Almost every mine that has been productive is given a thorough geologic study before it is abandoned. Any geologist will appreciate the value of properly preserved rock specimens, especially if properly correlated with the mine workings. Many places which are now inaccessible might have to be re-opened in order to give sufficient knowledge to draw intelligent conclusions. Rock specimens from some of these places frequently might save this expense.

CRUDE petroleum from different districts may vary greatly in appearance. Samples may differ notably in color. By reflected light, as seen in a pail or other container, oil is commonly green, but it may be any one of several shades of green, or it may be black, brown, or yellow. Most of the petroleums from California, from the Gulf coast of Texas and Louisiana, and from Mexico are black or dark brown. Most of those from Wyoming, Kansas, and Oklahoma are green. Most of those from the Appalachian field are green or yellow. All the more productive oil districts of the United States, however, yield both dark and light oils. The color of petroleum as viewed by transmitted light—that is, as seen in looking through a clear glass container full of oil—may differ as much as it does when viewed by reflected light. It is most commonly some shade of brown, but it may be yellow or green, or, rather exceptionally, it may be coal-black. The color of oil is a rough indication of its value. Oils of the lightest color are generally the most desirable. The typical Pennsylvania oils, which have a higher market value than all others, are amber, light brown, or light green. Dark oils are rarely seen in the Pennsylvania district, and such as are obtained there have a comparatively low value.

THE following list gives the compounds in which the metals are most frequently found in nature:

Aluminum as the silicate.
Antimony as the sulphide.
Arsenic as the sulphide.
Barium as the sulphate.
Bismuth as the oxide, sulphide. Also metallic.
Cadmium as the oxide, carbonate, and sulphide.
Calcium as the carbonate, sulphate, and silicate.
Chromium as the oxide.
Cobalt as the sulphide.
Copper as the sulphide, oxide, and carbonate.
Iron as the oxide, sulphide, and carbonate.
Lead as the sulphide.
Magnesium as the carbonate, sulphate, and silicate.
Manganese as the oxide.
Mercury as the metal or sulphide.
Nickel as the sulphide.
Silver as the metal or sulphide.
Sodium as the chloride and silicate.
Strontium as the carbonate, sulphate, and silicate.
Tin as the oxide.
Zinc as the oxide, carbonate, and sulphide.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

DIVIDEND DECLARED BY GRANITE GOLD COMPANY OF CRIPPLE CREEK.

BLACK HAWK.—The Denver Mining Pool, recently incorporated, has erected a shaft-house and installed a hoist on its properties, comprising three patented claims situated between the Hard Money and Alaska mines in Gilpin county, both old-time producers. A two-compartment shaft is now being sunk to a depth of 150 ft., at which point cross-cutting will be started to cut the known McIntosh, Anna, Belford City, and Atlantic veins, traversing the property. A vein cut at depth of 80 ft. contains lead-silver sulphide ore. The two trial shipments made from the property settled as follows: No. 1, 127 oz. silver, 0.02 oz. gold, and 8% lead; No. 2, 283 oz. silver, 0.08 oz. gold, and 15.5% lead. The Alaska mine, just south, is making heavy shipments of mill and smelting ore to mills in Black Hawk and smelter at Pueblo.

CRIPPLE CREEK.—The Granite Gold Mining Co. will pay stockholders a 3c. dividend, totaling \$52,500, on February 10. With this dividend stockholders will have been paid \$420,000. The last dividend was paid in March 1918. This is the first dividend by a Cripple Creek company this year. High-grade ore has been found at a depth of 2450 ft. in No. 2 shaft of the Portland mine, on Battle Mountain. The Roosevelt tunnel lateral connects with the Portland shaft at 2131 ft., so that the new discovery is 319 ft. below the tunnel-level and at an elevation of 7794 ft. No assays have been made public, but miners assert the ore will equal in value the rich ore mined at the 23rd level. Arrangements are in progress to resume operations at the main shaft of the Elkton Consolidated Mining & Milling Co. on Raven hill. No work has been done on company account for more than two years.

DENVER.—The State Industrial Commission has formally notified officials of 47 metal-mining companies in Colorado, of a hearing scheduled for February 15, to investigate the proposed reduction in wages announced as effective March 1. No serious protest to the 50c. cut is anticipated, but all parties concerned will be given the opportunity to be heard. Legislative investigation of the State School of Mines was favored by the House of Representatives by a vote of 53 to 7.

КОКОМО.—Machinery will be installed as soon as railroad connections are made and machinery is delivered at the Uthoff tunnel. The tunnel is now being cleaned out and re-timbered and enlarged. The Michigan adit will

shortly be connected by a raise of 100 ft. with the old Michigan shaft. It will be used as an ore-chute for ores from the Snowbank and new workings of the Michigan mine. New ore-bins have been constructed. The Michigan is now marketing 1500 tons of ore monthly.

LAKE CITY.—Returns from a consignment of sacked ore, from the Little Chief group, shipped to the Pueblo smelter, show settlement made with the Standard Mines & Development Co., operating under lease and bond, of 55.9 oz. silver per ton. The ore was entered unexpectedly while driving from the discovery vein, opened in the No. 4 tunnel. The mine is in the southern section of the San Juan Triangle. Ore from the surface workings on the discovery vein, with silver at 60c., brought from \$128 to \$1000 per ton. The vein cut by the present workings is believed to be a parallel vein or the main vein with altered dip. Plans have been made for building a mill and for increasing the operating force.

OURAY.—The Mountain Top Mining Co. is sinking its main shaft and is mining good ore while sinking. Electric pumps to handle a heavy flow of water have been ordered. Fifty miners are employed on the property, 42 on company account and 8 by lessees. Silver ore assaying 70 oz. per ton has been opened by lessees on the Spur group above Black Lake. The ore-shoot is 20 in. thick.

MICHIGAN

ALL MINES MARKING TIME.

HOUGHTON.—A little improvement in the copper-metal situation has been noted in the last two weeks in this district. From 60,000 to 75,000 lb. per day has been shipped from the Calumet & Hecla smelters and about 50,000 lb. per day has been going out from the Quincy smelter, most of it to the East for use by manufacturers of brass. No copper at all is being shipped from here to England and but little to Japan and Germany. Japan at present is getting most of its copper from the Western mines. Shipments have been made, however, to Sweden and France, France being the best customer. Calumet & Hecla recently completed an order of 320,000 lb. of cake-copper for France. Shipments, however, are not making much of an inroad in the metal stocks on hand and copper is piling up on the local docks. Prospects for an early 'clean up' are not bright, although there is hope that the anticipated revival in the automobile industry in the spring and the contemplated nation-wide advertising campaign to encourage a wider use of copper will have a favorable effect on the market.

To effect further economy of operation, Isle Royale has closed its No. 6 shaft, which will remain idle until the market improves. This additional curtailment has thrown 70 men out of work. Only three shafts now are in operation, No. 5, 4, and 1, while three shafts, No. 2, 6, and 7, are shut-down. No. 4 and 5 are the best shafts, both of which are opened well ahead, with 75 to 77% of the ground available for mining. But little work is being done in No. 1, in which the quality of the 'rock' is not as good as that in No. 4 and 5.

Seneca, which suffered a mishap to its hoist, necessitating a suspension of hoisting for two weeks until the drum was repaired, is back on its regular program of development. The accident to the hoist, which affected only one of the two drums, did not interfere with the concreting of the shaft from the 6th to the 5th level and that work is nearing completion. The cross-cut from the shaft to the vein at the 6th level will be pushed through the lode in the course of a few days and drifting north and south then will be started. In the Gratiot shaft the raise from the 13th level is approaching the elevation of the 11th. This is all the work of this character that will be done in Gratiot, as the management considers it has accomplished its purpose in proving good stoping ground between these levels.

Victoria is one of the small properties of the district that has managed to operate, although with a greatly reduced force. Sixty men are employed, this force being about 25% or normal. Only one shaft, No. 2, is in operation, on one shift. No drifting or sinking is being done and the management is content merely to keep the mine open and its organization together. A little better than 100 tons of 'rock' per day is being hoisted. The present yield, with careful selection and including occasional mass, is averaging about 17 lb. per ton. Victoria probably will show a production of close to 500,000 lb. of copper for the year 1920, this being an estimate. Victoria is well opened ahead, with extensive drifts on all levels. The 'rock' mined is from the Forrest amygdaloid lode.

Arcadian Consolidated plans to investigate the ground north of its Arcadian and New Baltic shafts next summer. It is reasonably certain that mineralization in that direction exists. Some preliminary work already has been done. From the New Baltic shaft, on the 400-ft. level, a drift put in to the north opened well mineralized ground sufficiently encouraging to warrant further development to the north from both shafts. It is the intention to run drifts from both shafts simultaneously. In the meantime the work of sinking the New Baltic shaft proceeds in the lode.

NEVADA

BORAX MINE NEAR DEATH VALLEY JUNCTION WILL RESUME SHIPMENTS.

VIRGINIA CITY.—The Mexican mill is treating Consolidated Virginia ore at a rate of more than 500 tons weekly and another filter is being added to increase the capacity from the present 80 to 85 tons up to 150, so that

ore from other north-end mines can be handled in addition to an increased tonnage that is expected from the Consolidated Virginia, where new finds on the 1650, 2150, and 2250-ft. levels are providing the greatest tonnage in recent years. The find on the 1650, reported to be a 10-ft. width of \$40 to \$50 ore, was made in the burned area, and the full width of the orebody has not been determined. This level is producing 200 to 250 tons weekly of \$5.50 to \$8.50 ore, and stoping also is being done on the 1950, 2050, 2150, and 2250-ft. levels. A new station has been cut above the 1750-ft. level of the C. & C. shaft and a station at a corresponding depth has been cut in the Union shaft. A drift has been started from the Union shaft and it will be driven to the Sutro tunnel south of the shaft and eventually connection will be made with the C. & C. shaft, the passage forming a new haulage-way that will form a connection between all of the north-end mines and the Union shaft and will make more economical the carrying of ore to the Mexican mill. A Hoar shoveling-machine is being used in the United Comstock tunnel, the first time such a machine has been used in the mines of the Comstock. It is expected that construction of the mill will be started early in the spring, as a spur from the railroad to the mill-site will be finished in March. The increase in the number of men employed at Virginia City and Gold Hill has created a housing shortage for the first time in many years.

JARBIDGE.—The Elgoro company at Jarbidge recently shipped through Twin Falls, Idaho, \$174,000 worth of gold bullion, the output of the cyanide plant for one month. The Elgoro is a Guggenheim corporation that owns the Long Hike and other mines. It is the largest producer of gold bullion in Nevada at the present time.

GOLD CIRCLE.—A 4-ft. width of ore assaying \$100 to \$200 in gold and silver, with narrower veinlets included in this 4 ft. that assay as high as \$2000, has been opened on the 750-ft., or bottom, level of the Elko Prince. This ore-shoot was found last summer, but the pumps could not control the flow of water and the workings flooded to the 600. Some of the ore from the new shoot, being treated in the Elko Prince mill, is said to assay \$600.

PIOCHE.—The 200-ton mill being built by the Pioche Mines Co. will be completed in less than six months. Mill tailing of the Prince Consolidated at Bullionville and Dry Valley, estimated at 100,000 tons, is to be treated under an agreement made with E. R. Richards and Maurice Peterson of Salt Lake City. Richards formerly was metallurgist for the Chief Consolidated at Eureka, Utah. The capacity of the old Bullionville mill is to be reduced from 200 to 100 tons to obtain a better extraction. The tailing, which contains an average of 10.6 oz. silver, 5.3% lead, and 0.11 oz. gold, is seven miles distant on the railroad from the mill.

DEATH VALLEY JUNCTION.—It is reported that the Pacific Coast Borax Co., which recently closed the mines situated in Death valley, is to resume work in the near future. The mines were closed because of high freight-rates to the Atlantic coast, and it is said the com-

pany plans to ship by rail to San Pedro, California, and from there to Eastern points by boat. Shipments were made last year at a rate of about 6000 tons monthly and it is pointed out that the company can ship a boatload monthly from San Pedro. Men who have been at the mines in the last few days say the entire crew was not laid off and that a large quantity of borax is piled awaiting shipment. The company has a factory in California that supplies the demand of the far West, and the Eastern factory is at Bayonne, New Jersey.

UTAH

TINTIC STANDARD MILL STARTS OPERATION.

PARK CITY.—While the directors of the Silver King Coalition Mines Co. have not announced definite plans as to re-building the concentrating plant destroyed by fire

company has been making regular shipments. During January, about 90 loads, or approximately 250 tons, of ore were transported by teams from the bins to the railroad. Charles M. Evans, superintendent, reports that some excellent ore has been opened recently.

EUREKA.—The shaft at the North Standard property is nearing the 1100-ft. level, and it is the intention of the management to continue sinking until the 1150-ft. level is reached, according to John Manson, manager. The bottom of the shaft is now in a limestone-quartz, which contains some gold and silver. When the 1150-ft. level is reached, drifting will be started, as geological conditions are such that ore is expected at that depth. An assessment was recently levied on the stock of the Imperial Lead Co., whose property is in the western part of this district. During 1920, the company produced a sub-

VIRGINIA CITY, NEVADA, THE SCENE OF REVIVED ACTIVITY

on January 27, local officials are of the opinion the plant will be re-built. Undoubtedly if a new plant is constructed, it will provide for flotation-treatment, as the tests carried on recently have been satisfactory, although it is not deemed advisable to supplant the wet-concentration method by flotation exclusively.

During the week ending January 29, shipments from this district totaled 2071 tons, of which the Judge allied companies shipped 1054; Silver King Coalition, 497; Ontario, 405; and Naildriver, 115. The Judge smelter shipped 50 tons of premium spelter.

ALTA.—A carload of ore has been shipped by the Wasatch Mines Co. to a Salt Lake Valley smelter, according to J. E. Beveridge, manager. A promising part of the company's holdings is now being explored by a drift along what is considered the Cardiff over-thrust contact. This work is being done about 6000 ft. from the portal. For the last 250 ft., ore has been found in small bunches and in stringers. Owing to the excellent condition of the road in Little Cottonwood canyon, the Columbus Rexall

stantial tonnage of lead ore, and officials state that development will be resumed this spring. At the Utah Zinc Co.'s mine, development work has been carried on during the present winter, and several carloads of lead-zinc and silver-lead ore are awaiting shipment, according to B. F. Fleiner.

Shipments from the mines in this district totaled 172 carloads during the week ending January 29, of which the Tintic Standard shipped 63; Chief Consolidated, 34; Iron King, 16; Eagle & Blue Bell, 15; Dragon, 14; Iron Blossom, 11; Victoria, 7; Grand Central, 3; Centennial-Eureka, 3; Swansea, 2; Gemini, 1; Eureka Mines, 1; Colorado, 1; and Sunbeam, 1.

About three cars of ore per day are being shipped to the new mill of the Tintic Standard Mining Co. Five of the seven roasters are in commission, and aside from a few mechanical adjustments, operations are reported as satisfactory. C. W. Frith, for some time past metallurgist at the Tintic Milling Co.'s plant, has been appointed assistant superintendent of the mill.

BRITISH COLUMBIA

ONE SUIT INVOLVING PREMIER MINE DISMISSED; ANOTHER STARTED.

STEWART.—Action brought by Maurice W. Bacon against R. K. Neill, one of those interested in the Premier mine, for the recovery of a one-quarter interest in the property has been dismissed by Federal Judge E. H. Rudkins, in the courts at Spokane. The latter in his judgment states that the plaintiff in two cases had influenced witnesses and had lacked good faith in not bringing the suit in 1917 when he first knew of Neill's operations, instead of waiting until the mine had proved of worth. Patrick Daly, of Nelson, B. C., is suing R. K. Neill, R. W. Woods, A. B. Trite, and W. R. Wilson, all of whom are interested in the Premier mine, for a one-fifth interest in the same. He alleges that Neill entered into an agreement with him to finance the development of the property and to give him the share he is asking for. This undertaking, he asserts, was approved by the other defendants when they became partners.

P. S. Jack, who for the past five years has been mining recorder here, has been made business manager for the Algonian Development Co. A considerable amount of development has been done at the Nabob group, but a good deal of it appears to have been misdirected. An adit was driven a considerable way before it was discovered that it was parallel to the vein. A cross-cut was then run, and a raise put up, but the ventilation was so bad that the work had to be suspended. Another tunnel was then driven, and this has penetrated a 12-ft. vein, showing free gold. Work has been stopped until the spring.

ASHCROFT.—A large quantity of hydraulic placer-mining machinery is being moved from the Bullion and Horsefly mines in the Cariboo district, by R. T. Ward, who recently sold these claims after successfully asserting his title, and that of his associates, in a legal battle with John Hopp, which was carried to the Privy Council, England. The claims are said to have changed hands at a considerable figure and the nature of future operations is such that the long disused equipment is not required.

NELSON.—The Columbia section of the American Institute of Mining Engineers, whose membership is taken from the North-Western States, will hold sessions next summer at Nelson and Trail, the dates to be arranged to coincide with those of the International Mining Convention to be held at Nelson. It is likely that these joint gatherings will take place sometime in June. S. G. Blaylock, general manager for the Canadian Consolidated Mining & Smelting Co., has promised his cordial co-operation in the endeavor to entertain the visitors.

ONTARIO

MINES AT PORCUPINE PLAN TO INCREASE SCALE OF OPERATIONS.

Preparations by the Imperial Oil Co. for the resumption of oil-drilling and prospecting on an extensive scale in the Canadian North-West have been suspended as a

result of the recent suspension by the Government of the regulations for the disposal of petroleum rights. C. O. Stillman, president of the company, said that the action of the Government had come as a complete surprise, and they were unwilling to take any further steps in the way of resuming operations until the Government policy had been announced. This, he added, is still the attitude of more than a score of local syndicates and small Western prospecting companies. The interests involved are of such importance in their relation to the opening up of the North-West that it is not likely that the adoption of a permanent policy in regard to the question will be long delayed.

PORCUPINE.—As abundant labor is now obtainable, the increase in the supply of power in the spring will result in a large increase in gold production. The leading mines are preparing for increased output. The Hollinger, it is expected, will be treating at least 3000 tons per day by early summer. The Dome Mines can handle 1350 tons per day, as compared with 400 tons at present, and the McIntyre is prepared to treat 600 tons in place of something less than 400 tons, which is the limit under existing conditions.

Negotiations looking to an amalgamation of the West Dome and the Dome Lake are well advanced. The merger would be to the advantage of both companies as the Dome Lake veins extend into the West Dome territory, and the Dome Lake shaft could be used economically for the extraction of ore. It is reported that the Keora has cut another rich vein on the lower levels, confirming the indications of diamond-drilling showing high gold content.

KIRKLAND LAKE.—It is officially announced that operations on the Bidgood will be resumed. The capacity of the present mining plant will be doubled. The shaft now down 300 ft. will be sunk further. D. H. Angus, formerly manager of the Tough Oakes, has been appointed manager. Operations have been started on the Kitchener-Kirkland in the Goodfish Lake section of the camp, where a force of 12 men is at work. The big new mill of the Wright-Hargreaves cannot go into operation before spring, as power is not obtainable.

COBALT.—The mines which remain open are working steadily and no further curtailments are anticipated.

The Primo Silver Cobalt Co. has been incorporated for the purpose of taking over and operating the Barber property, which lies in the western part of Coleman township. A small mining plant has been purchased and is being transported to the property. Several veins have been opened in which silver is found; one vein about 18 in. wide contains 5% cobalt. Sinking is to be commenced, with effort directed toward developing silver ore from which cobalt can also be obtained as a by-product.

BOSTON CREEK.—At the Miller Independence the cross-cut north from the 500-ft. level of the main shaft has reached a length of 530 ft., and has penetrated numerous veins, the most important being the one already showing in the face. The cross-cut will be continued to the northern boundary about 150 ft. further to reach what is believed to be the chief area of mineralization.

COPPER PRODUCTION

The following list shows the output of the leading copper producing companies during 1920 as compared with 1918. The figures are pounds. The same companies in 1919 produced a total of 1,045,229,733 pounds.

Company	1920	1918
Ahmeek	20,489,338	24,851,235
Allouez	2,499,239	7,071,218
Anaconda	160,450,000	293,603,726
Calumet & Arizona	40,866,000	51,357,154
Calumet & Hecla	57,618,683	67,968,357
Centennial	561,284	2,492,857
Cerro de Pasco	52,810,000	71,906,000
Chino	45,705,490	76,635,641
East Butte	18,773,200	25,091,000
Granby	27,101,035	38,808,515
Greene Cananea	43,458,000	53,349,515
Inspiration	81,250,000	98,540,041
Isle Royale	10,621,201	15,442,508
Mohawk	10,269,324	10,781,041

Utah	102,573,942	188,092,405
White Pine	1,852,787	3,273,680
Wolverine	3,299,286	4,242,787
Total	1,066,687,868	1,625,420,814

PETROLEUM PRODUCERS PROTEST MEXICAN PLAN FOR TAXATION

Formal objections to the Government's projected law providing for the payment of taxes on oil were presented to Adolfo de la Huerta, secretary of the treasury, on February 2 by a committee representing the Association of Producers of Petroleum in Mexico. Assertion was made by members of the committee that it was the most energetic protest as yet made to the Government by the association. The memorandum contained charges of "subterfuge" in the designation of the act, and a declaration "that companies which export petroleum are subject to maneuvers which can be arbitrary on the part of officials or the employees of the secretary of finance". It is alleged the projected legislation would levy exorbitant taxes wholly out of proportion to the value of the product. Declaration by the Government that the proposed law would provide for a production tax, was denied by the protest, which asserted the only portion of oil production affected by the tax would be that which includes crude petroleum and its products exported from Mexico. "Exorbitant increases in the tax to be levied on petroleum are provided for in the proposed law," said the memorandum. "For instance, Panuco crude petroleum would bear

a tax of 41% of its total value, or four out of every ten barrels; Tuxpam crude would be taxed 28%, or nearly three barrels out of ten, and fuel-oil would bear 31% tax, or one barrel out of every three produced. Such a tax would ruin any business."

It was stated semi-officially that administration officials had combined to push the projected law during the coming session of the Mexican congress, and it was declared that President Obregon would urge a specific provision in the law stating that article 27 of the constitution, which would nationalize oil deposits would not be retroactive. The President has on several occasions declared this was his view of article 27.

ZINC-OXIDE PLANT OF THE AMERICAN ZINC, LEAD & SMELTING CO.

At its new plant erected in Columbus, Ohio, for the production of lead-free zinc-oxide, the American Zinc, Lead & Smelting Co. is getting some highly satisfactory results. This manufacturing unit was completed last fall at a cost of \$750,000. It has a rated annual capacity of 7500 tons of zinc oxide, the ingredient so necessary in the construction of automobile tires. At present the plant is producing at the rate of 3750 tons annually, or 50% of capacity. It was unfortunate from the trade standpoint that American Zinc company's new plant should come into production at just the beginning of the depression in the tire industry, but though present output of 50% capacity naturally cannot permit of much profit, the officials are gratified at the excellent results being obtained from all departments. Having its own supply of high-grade zinc ore at its Mascot mine in Tennessee, the American Zinc company is expecting to get a substantial amount of business when the tire companies resume greater production. With production at or near the new plant's capacity, the American Zinc company expects earnings from the zinc-oxide business alone that will provide the \$6 dividend on the 80,540 shares of preferred stock held by the public.

ALASKA

Hyder.—The steamship 'Albert' is due with 240 tons of machinery for the Premier mine. A large part of the shipment is cyanide for use in the mill now nearing completion. The wharf at Hyder is not sufficiently large to accommodate the incoming freight and outgoing ore and will be enlarged. Approximately 400 tons of ore valued at \$500 per ton will be shipped on the return trip of the 'Albert'.

CALIFORNIA

Amador County.—The supply of labor in the Sutter Creek and other districts is adequate and operations on a larger scale have been commenced at several of the mines. The Central Eureka stamp-mill is now running at full capacity of 40 stamps instead of 20 stamps, as formerly.

Work is progressing at the Fremont Consolidated and Bunker Hill, two well known Amador producers recently rehabilitated after long idleness. Improved labor efficiency and lower prices of materials used in mining are proving advantageous.

Nevada County.—The United American Mining Co. has recently taken over the Ironclad mine in the Rough and Ready

district. H. M. Black has employed a number of miners and will increase his force soon. The Ironclad lode was discovered in 1878 and at that time several shipments of ore valued at \$17.50 per ton were shipped to the old Southern mill at Grass Valley.

Plumas County.—With the mill treating ore from the Engels and Superior mines, the Engels Copper Co. continues to produce at a good rate despite the many unfavorable conditions affecting the copper industry. Considerable gold and silver in Engels ores materially aid operations, as the profits derived from the precious metals compensate for lower copper prices.—The Mason Valley Mines & Smelter Co. will start work at its holdings on the Plumas copper 'belt' soon, according to reports.—Development work only is being done at the Walker copper mine.

San Bernardino County.—W. H. Voyles and associates, of Salt Lake City, are prospecting a rich vein of gold-silver-copper ore situated just over the mountain from the Ivanpah mine, from which several million dollars worth of rich silver ore has been mined. The new mine is called the Sunshine Silver. A shaft has been started, at the bottom of which is a 15-in. vein assaying 375 ounces of silver and containing in addition 29% copper. The nearest railroad point is Cima on the Salt Lake route, and economical transportation will be one of the problems to be solved.

Sierra County.—W. W. Casserly, superintendent of the Kate Hardy mine at Forest, will install an air-compressor of capacity sufficient to operate 20 drills and will begin work on the erection of a 10-stamp mill as soon as weather permits.—At the Mugwump gravel mine Dennis Coughlan is increasing the force of miners, following a 'strike' of particularly rich gravel.—George F. Stone is developing and blocking out ore on the North Fork property.—At the Diadem quartz mine an electric hoist and sinking-pump, direct-connected to an electric motor, a hoisting cable, and a mine-skip have been received in anticipation of active work in the spring. The mine was recently bonded and the lessees have placed J. E. Osslin in charge of operations.

Sonoma County.—Charles A. Peary of Healdsburg has patented a process for recovering fine gold and platinum from 'black sand'. The device is briefly described by a correspondent as follows: It consists of a bucket, containing a hopper which sets in the head, an inverted cone set some inches above the bottom of the bucket, and a water-pipe which projects through the bottom and supports the cone by means of brackets. Water is forced through the pipe and inside the cone and upward through the hopper. The sand or fine crushed ore is fed into the hopper. The water being deflected downward by the cone and then finding its way to the top causes agitation of the mass in the bucket and the waste or residue flows over the edges of the bucket. The heavier material such as fine gold, sulphides, black sand, or platinum will settle to the bottom and concentrate, the lighter material running off. The feeding is a continuous process and may be continued until such time as it is necessary to make a cleanup. In a plant where the sulphides or metal may tend to clog the free flow of water from under the cone, buckets may be arranged in batteries and some be used while others are being cleaned. It is impossible to clog the flow of the machine as long as the concentrates are not allowed to accumulate to too great an extent.

COLORADO

Grand Junction.—The Western Shale Oil Co., after a year of experimentation, has started operating a 50-ton unit at its plant here. The Gallop process is used, the latest designed furnace having effected a saving of 40% in fuel over that consumed by the earlier type. It is expected to mine by an open-pit method for \$1.25 per ton, to grind the shale in an American pulverizer for 30c. per ton, and to retort for 30c. per ton, making a total cost of \$1.85. The oil will be

refined at the plant of the Apex Refining Co., of Denver, where, after removing gasoline and perhaps kerosene, an excellent oil for use in flotation plants will remain.

Idaho Springs.—The Gem company is making shipments of 50 tons daily to the smelter, while a lower-grade product is being sent to the Newton mill now operating steadily on three shifts. The drift has been advanced 400 ft.—Returns from a recent shipment of ore from the Dunkirk mine, made by the Mitchell lessees, netted \$241 per ton. A second lot of ore not quite so high in grade is ready for shipment.

Leadville.—An agreement has been reached between the Leadville Mine Development Co. and the Leadville Land & Water Co., whereby the latter will allow the mining company the privilege of dumping on its land. The adit will be commenced at once.

IDAHO

Boise.—The annual meeting of the Idaho Mining Association was held here on February 11 and 12. Among the subjects discussed were the following: the tariff question, the Kitchin revenue act, the alleged injustice done the locator of mining claims by the 640-acre enlarged homestead act, and the proposed change in the date for completing annual assessment work. D. H. Ferry, manager for the Yukon Gold Co., and Walter C. Clark, of the Bunker Hill & Sullivan company, gave illustrated lectures.

Coeur d'Alene.—The Big Creek district known as a silver-bearing belt is attracting unusual attention owing to large amount of development work under way and the erection of the second concentrator on the creek. Steady shipments are going to the smelter from the Big Creek Mining Co. Equipment for the 50-ton concentrator for the Sunshine Mining Co., operating the Yankee Boy and Yankee Girl properties, is on the ground and it is planned to have the mill in operation early in the spring.—The Sterling Silver Mountain company is developing a group of claims adjoining the Yankee Boy. A blind vein was cross-cut near the 500-ft. station, showing a width of eight feet containing gray copper. A drift will be started on this vein and at the same time the main cross-cut will be continued toward its objective, which will be reached in 300 feet.

The new freight-rates from Coeur d'Alene points to the Northport and East Helena smelters effect a big saving on the higher-grade ores, and under the least favorable conditions are 50c. per ton lower than the old rates, while the greatest saving is \$5.37½. The ores chiefly affected are the Hercules and Tamarack & Custer going to Northport, and the company ore and that of the lessees in the Morning mine of the Federal company, which goes to East Helena. The new rates are \$3 per ton for \$30 ore and an increase of 25c. for each \$10 increase in value of the ore up to \$4.75 for \$100 ore. Above \$100 there is a flat charge of \$5. The old rates were \$4.25 per ton for ore under \$60, \$6.25 for ore between \$60 and \$65, and between \$65 and \$100, 9.37½.

In the Pine Creek district the development work is under way on the property now owned by the Jim Blaine Silver syndicate. The company is developing a mineralized belt by means of a long cross-cut tunnel, designed to give approximately 700 ft. vertical depth on three veins, namely, the Bristol, Midnight, and Constitution. The Jim Blaine company has a good silver-lead ore in its upper workings. The company recently consolidated three well-known groups, the Bristol, Jim Blaine, and Chesapeake, comprising 500 acres in the heart of the mineralized zone of the Pine Creek belt.—Drifting on the 400-ft. level of the Chicago-Boston property has been extended for 40 ft. east on the vein with no ore yet. The condition of the vein remains the same as it was a week ago when it was first crossed by the drift from the new 400-ft. level of the shaft. Stringers of high-grade ore have been present, but nothing like a good body of ore has yet been found.

MISSOURI

Joplin.—Walter Carter, while drilling a well on his farm near Cartersville, found a deposit of lead ore at a depth of 90 ft. The deposit at that point is 20 ft. thick. A shaft is being sunk to mine the ore and prospecting in the vicinity is being done by numerous land-owners.—A new company, composed of Pittsburgh capitalists, has purchased the Morning Star, Capps, Carney, Philadelphia, and Red Cloud mines in the vicinity of Rush, Arkansas. They expect to be ready to commence operations when the prices of metals improve.

MONTANA

Great Falls.—The zinc refinery of the Anaconda Copper Co. was shut-down February 1. The smelter, which handles zinc residue, will continue to operate for 30 days. About 1500 men are employed in the two departments. The copper-wire mill, the electrolytic copper refinery, and the copper furnace refinery, in which about 600 men are employed, will continue operation.

Helena.—It is reported that the Barnes-King Development Co., which recently acquired the Black Hawk claim in the Marysville district, has uncovered the Penobscot vein.—Work has been started on the construction of the new mill of the Alta Consolidated Co. at Corbin. The mill will first re-treat the tailings dump from former operations. S. L. Bright, of Chicago, an official of the Alta company, has been at the property.

Neilhart.—Regular shipments are being made from a number of mines in the district. Ten cars were shipped from the Hartley property during January. The low price of lead is materially decreasing the profit on the ore.—Liscomb & Parmeter, lessees at the Flohart property, are mining ore regularly from their block of ground situated above No. 2 tunnel.

Townsend.—A vein of good galena ore from 2 to 5 ft. wide has been penetrated by the Iron Mask adit. Butte men during the past two years have spent more than \$200,000 driving this adit.

White Sulphur Springs.—The first carload from the Willow Creek mine has been shipped. The railroad company has promised to build a sidetrack to facilitate loading ore.

NEVADA

Eureka County.—The Eureka-Holly mine is producing more than ordinarily high-grade ore from the 500-ft. level. The drift on the 600-ft. level has 80 ft. more to run to get under the same ore-shoot. On the 400-ft. level a large quantity of ore is being broken, ready for treatment in the mill, as soon as the latter is ready to operate. It is estimated that there is ore worth \$700,000, which may be profitably treated in the mill.—The water in the Locan shaft, on Ruby hill, was drained to within 18 in. of the bottom, admitting of the removal of debris that had accumulated. Edward Holter, of New York, president of the Ruby Hill Development Co., and Howard D. Smith, a director, have been visiting the mine. Previous to their inspection of the Richmond-Eureka mine they were two weeks in San Francisco. Since their departure, a report has gained circulation that operations in the Locan shaft are suspended indefinitely, but no information can be had from anyone in authority. There is considerable surmise as to the aims of the Ruby Hill Development Co. It has, it is said, until next December to sink the additional 500 ft. of the Locan shaft and take over 59/100 of the holding stock. There seems to be no doubt on the part of geologists that the lower wedge

of limestone would prove as productive as the upper wedge.

Lone Mountain.—The Electric Gold Mines Co., promoted by Frank E. Horton, manager of the Dalsey in the early days of Goldfield, has sunk an 85-ft. shaft and has sampled the workings of the old Weepah, five miles west of the West Divide mine. The bottom of an 18-ft. single-compartment shaft is in \$14 ore. The silver content is small. The company is improving the road to the mine and when this has been completed an 18-hp. hoist will be moved to the claims.

Manhattan.—The American Onyx Co., operating a mine owned by Robert Maris, recently made a shipment of tubemill pebbles to the MacNamara mill at Tonopah. The product of the American Onyx is pebbles of silicified rhyolite, the market for which is reported to be improving after having had strong competition from Denmark. It is reported that the White Caps is to add a third shift of contractors in the mine. The cross-cut on the 800-ft. level is 325 ft. long.

Mina.—An electric power line from Millers to the Simon district is being surveyed by E. W. King, chief engineer for the Simon Silver-Lead company, and construction will commence some time this month.

The distance is about 38 miles. The line will be constructed and owned by the Simon Silver-Lead Mines Co. and will serve other properties that desire power. The Nevada-California Power Co., which will supply the power, has an application pending before the public service commission to discontinue the line from Aurora to Hawthorne, which has been set for hearing February 3. If the petition is granted the transformers, wire, and poles on that line may be purchased for the Millers-Simon line. Construction of the 150-ton mill at Simon is progressing rapidly and it should be ready to operate early in the spring.

OKLAHOMA

Picher.—In spite of the numerous shut-downs during recent months, about 70 mines, employing 2000 miners, are producing on a curtailed basis. Wages have been reduced throughout the district, and every possible measure of economy has been instituted. A few properties are being operated at Treece and Baxter Springs, Kansas, and near Hockerville and Zincville, Oklahoma.

UTAH

Gold Hill.—Daily shipments of 300 tons of low-grade fluxing ore are being made to the smelters from the mine of the Western Utah Copper Co. The company has made no reduction in wages, the rate still being \$6 per day. Excellent efficiency is being obtained and mining costs are said to be lower than in any other underground mine in Utah. On the 700-ft. level a cross-cut is being run to cut the ore-shoot at a lower depth.

Price.—The Ohio Oil Co., the Carter Oil Co., and the Midwest Oil Co. are prospecting on the San Rafael swell 50 miles south-east of here. Near Huntington the Ohio company has started an 18-in. hole; it is planned to sink to 3500 ft. should the expected sand at 1800 ft. prove unproductive.

Eureka.—Rescue car No. 11, of the U. S. Bureau of Mines, arrived here this week. The car, in charge of Carl Allen, is stationed near the Bullion-Beck mine. With him are Dr. Murray, Bruce Johnson, and R. W. Clark. Mr. Allen states that the car will be kept here for several days, during which time men from various Tintic mines will be instructed in first-aid and rescue work.

WASHINGTON

Colville.—Two carloads of lead-silver ore have been shipped from the Old Dominion mine. The mine is operated by the Dominion Silver-Lead Mining Co., of which W. H. Linney, of Spokane, is president and manager. In the early days ore was hauled to Spokane in wagons. For a number of years the property was idle on account of litigation, which was cleared up last year. Several months ago a new company started work.

Northport.—The Indian Chief Mining & Milling Co. has been incorporated for the purpose of developing the Indian Chief group of five lead-silver claims near here. The capitalization is \$50,000.

Chewelah.—Plans for the consolidation of the United Silver Copper Co. and the Copper King Co., which own contiguous claims near here, on the basis of an issue of 1,800,000 shares of new stock at a par value of 25c. per share were presented to stockholders of the United Silver Copper Co. at a meeting held recently. The company during 15 years has produced \$2,000,000 in silver and copper ore and paid \$140,000 in dividends. It is incorporated for \$1,000,000. The Copper King has a large deposit of low-grade copper ore.

Spokane.—The Washington State Metal Mines Association re-elected the following officers at the annual meeting held recently: L. K. Armstrong, president; E. H. Knight, vice-president; M. E. Poole, secretary-treasurer. The following, together with the officers, constitute the board of trustees: H. S. Stoolfire, M. J. Sweeny, Dan Bagnell, J. L. Drumheller, and J. C. Haas.

MEXICO

Tampico.—The Mexican Petroleum Co. has mapped out an extensive development program for the current year, the largest item being the erection of a loading-station at Port Lobos, to be the terminus of a new 10-in. pipe-line from country south of Cerro Azul. At present the bulk of its oil is moved to Tampico, but as an extensive drilling program in the new southern territory is indicated, a loading-station at Port Lobos would be a great deal nearer than the station at Tampico. The company is building an addition to its railroad to permit transportation of needed materials for drilling in the southern district where 12 wells are being drilled. With five permits just received that had been held up by 'denouncements' under Carranza decree, the number of new wells is increased to 17.

Torreón.—The smelter here will resume operations soon. A few shipments of ore are now being received and a good supply of fuel is on hand. The Mapimi smelter, owned by the same company, the Metales y Minerales, will not be blown in until later. The ores from the mines of the company will be brought to Torreón for smelting in the meantime.—Martin C. Piton, prominent mining man of the Mapimi district, has filed on a large group of mines in the Cerro Blanco, under the name of La Tempiquena. He has taken out some fine specimens of silver and lead ore and anticipates being able to make shipments to the smelter soon.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

S. H. Dolbear has gone to New York.

W. L. Honnold, of New York, was here last Saturday.

M. L. Requa has returned from New York to San Francisco.

John B. Richards, of Bishop Creek, California, has gone to Spokane.

John P. Benson has returned from Mazatlan, Mexico, to Berkeley, California.

R. C. Gemmell and **D. D. Moffat** have been in New Mexico and Arizona.

A. M. Yonge has returned from Porto Rico and is now living at Berkeley, California.

Paul Lincoln, manager of the Noble Five, at Sandoz, B. C., is in San Francisco on a holiday.

Charles Bunting, locator of the Premier mine, in British Columbia, is at the Merrimac hotel.

J. M. Callow, of the General Engineering Co., of Salt Lake City, has returned from Superior, Arizona.

C. G. Newton, of Seattle, formerly with the Yukon Gold and Braden companies, is in San Francisco.

Ernest Bamberger, general manager for the Ontario Silver Mines Co. at Salt Lake City, is in New York.

George S. Ritter sailed on February 8 for Manila, where he will join the staff of the Benguet Consolidated Mining Co.

Stuart Croasdale and his associates, of Denver, have opened an office at Pittsburgh under the name of Stuart Croasdale & Co.

James Frame will spend six weeks or two months at Chalchihuites, Zacatecas, Mexico, where he is examining several mining properties.

G. W. Heintz, of Boston, vice-president in charge of Western operations of the United States Smelting, Refining & Mining Co., is at Salt Lake City.

G. B. Dennis, for many years president of the Northwest Mining Association, has been made honorary president and a life member of the Association.

G. E. Stephenson has been appointed assistant purchasing agent for the Ray Consolidated Copper Co., to succeed **J. H. Browne**, deceased. Mr. Stephenson's headquarters are at Hayden, Arizona.

Solomon R. Guggenheim has been elected president and chairman of the executive committee of the Braden Copper Co., succeeding **W. C. Potter**, who recently resigned to become chairman of the board of directors of the Guaranty Trust Co. of New York.

Sir Ernest Oppenheimer, a director in diamond and gold mines in South Africa, is making an extended trip in this country, visiting mining and metallurgical plants. He is accompanied by **W. L. Honnold**, formerly consulting engineer for the Brakpan Mines, at Johannesburg. They spent a couple of days in Utah recently.

At the annual meeting of the board of trustees of the United Engineering Society, on January 27, the following persons were elected officers of the society for the ensuing year: president, **J. Vipond Davies**; 1st vice-president, **Calvert Townley**; 2nd vice-president, **W. L. Saunders**; secretary, **Alfred D. Flinn**; treasurer, **Joseph Struthers**; and assistant treasurer, **George H. Pegram**.

THE METAL MARKET

METAL PRICES

San Francisco, February 8

EASTERN METAL MARKET

(By wire from New York)

February 7.—Copper is quiet and firmer. Lead is inactive and lower. Zinc is lifeless and steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

REVIVAL OF BUSINESS

America does not need a boom period to be prosperous, and the substantial factors of our national wealth will eventually bring about adequate revival of industry and commerce, declares James S. Alexander, president of the National Bank of Commerce in New York.

There are at present a number of great business forces clearly at work building a sound business structure for 1921. Supply and prices are becoming broadly co-ordinated to demand. The improvement in the liquidity of credit, which is now in progress, must develop further, but there are signs that improvement there will continue. As these movements are fulfilled, as wages and labor are re-aligned to new conditions, and as business finally absorbs the losses incident to deflation, stabilization on the new level will become an accomplished fact.

Normal activity must come from within business rather than from without. Business cannot idly wait for the public to resume active buying. It must stimulate buying by establishing a wide prevalence of substantially reduced prices for goods which must be based on increased efficiency in production and distribution, and the acceptance of reasonable margins of profits.

In this connection the growing tendency of labor to become more efficient and its willingness to accept liquidation of inflated wages is a most encouraging circumstance. From more than one point of view the readjustment now going on in respect to labor supply and demand is beneficial to the individual worker. The excess of jobs over workers, inflated wages, and lax supervision from employers which characterized the 'boom' period were all bad influences upon labor and contrary to its best interests.

Radicalism, encouraged by labor scarcity, invaded and depreciated the quality of labor as a component in our national economic life. High wages begot extravagance that soon reacted in rising prices, reducing the buying power of those very wages so that labor's gain was more apparent than real. There also developed a demoralization of individual efficiency because men were not kept on their mettle by competition for work and advancement.

With the return of more rigorous conditions it is becoming clear that the best interests of conscientious labor are served by a more normally balanced relation between labor supply and demand. Competition for work means the stimulation of efficiency and staunch Anglo-Saxon individualism as opposed to socialism. An abundance of labor permits employers to choose workmen intelligently and to co-ordinate wages to their proper part in production costs, facilitating the establishment of price levels best for all.

But employers must play fair and not attempt to lower wages unduly or to enforce greater curtailment than circumstances warrant. They must recognize that, in any country worth living in, the standard of living tends ever upward. Wage earners in the United States are entitled to the opportunity to receive more than merely the means for a bare and joyless existence in return for real work well done. Any other attitude on the part of employers would be a menace not only to the orderly readjustment of existing conditions, but also to sound business progress in the long run.

I believe we are justified in confidence that these elements of progressive readjustments which are working toward better times are now greatly in the majority. The true need of business is, not stimulation of the forced-draught order, but rather a conservative response to better conditions as they develop.

MONEY AND EXCHANGE

Foreign quotations on February 8 are as follows:

Sterling, dollars:	Cable	3.88 1/2
	Demand	3.87 3/4
Francs, cents:	Cable	7.23
	Demand	7.20
Lire, cents:	Cable	3.70
Marks, cents:	Demand	1.68

Eastern Metal Market

New York, February 2.

Extreme dullness pervades nearly all the markets. Prices are steady for some metals and weaker for others.

Demand for copper does not improve but the price-level remains unchanged.

Transactions in tin have been moderately good and the price has been fairly steady.

Demand for lead has quieted down with a slight easing in values.

The zinc market is the weakest of all and quotations are lower.

Antimony is softer because of the sharp decline in silver.

IRON AND STEEL

Pig-iron output was about 300,000 tons less in January than in December, indicating that steel production also declined, though perhaps less. The pig-iron total for the country was 2,405,845 tons, or 77,478 tons per day, against 2,703,855 tons in December, or 87,222 tons per day, according to 'The Iron Age'. The Steel Corporation, however, added 35,000 tons to its December output, while the independent companies made about 170,000 tons less than in December and the merchant-furnace output declined about 165,000 tons.

There was a net loss of nine independent steel company and ten merchant furnaces last month, while the Steel Corporation's gain was one. Active furnaces numbered 183 on February 1, against 201 on January 1.

Reports of foreign pig-iron and steel offered in this country are quite indefinite. Belgian basic pig-iron at \$28 or \$29, Atlantic seaboard, is not attractive, the possibility of German bars at 2.10c. on this side has aroused no interest.

COPPER

There has been no improvement in domestic demand. The few sales being made have been taken largely by small producers at 12.75c., delivered, for electrolytic with 13c. asked for February-March. These are the prevailing quotations though some large producers are asking not less than 13c. for prompt and early delivery. Lake copper is largely nominal at 13.25c., delivered. The somewhat sensational announcement was made yesterday that the Copper Export Association has sold 200,000 net tons of copper to Germany, the financing having been arranged on this side. No details are available. In an attempt to confirm this report your correspondent consulted a representative of one of the largest producers whose company is a member of the export association. The report was characterized as 'bosh' and entirely unfounded. Further light on the subject will be awaited with interest. News and trade papers seem to credit the report and publish it as a fact.

TIN

For the first time in some weeks consumers have shown more interest which has resulted in purchases but this has not been heavy. On Monday there were sales of future shipment amounting to 100 to 150 tons, comprising March shipment at 34.25c. and April shipment at 34.75c. Dealers were not in the market that day, an unusual incident. During most of last week dealers were buyers, in a quiet way, of considerable metal. There is a disposition on the part of consumers to desire higher prices so that they can cut down their loss on the high-priced metal they hold in stocks and they therefore hesitate as to just what course to pursue. Their manufactured products are in slightly better demand but the improvement is not pronounced. Prices for spot Straits, New York, have hung between 33 and 35c. during the week with the quotation yesterday at 33c. In London there has not been much change; quotations yesterday were £168

10s. for spot standard, £173 15s. for future standard, £187 10s. per ton for spot Straits, all of which are a little higher than a week ago. There is a rumor, unconfirmed but credited as probable, that the Malay government will reduce on February 8 its minimum quotation to £205. Deliveries into consumption in January are returned as 1555 tons with 2546 tons in stocks and landing on January 31. Imports for January were 1245 tons against 4195 tons in January 1920. Tin afloat is reported as 1395 tons.

LEAD

The market is much quieter and easier. There is more metal offered than there are buyers and this has resulted in a softening in values. Quotations in the outside market are 4.60c., St. Louis, and 4.85c., New York. The leading interest continues to quote 4.75c., both New York and St. Louis. The premium on spot of a few weeks ago has disappeared, there being no demand for this delivery. The opinion is expressed that the market cannot go much if any lower for conditions do not warrant it. The previous low was 4.50c., New York and St. Louis, in December, and this point is not expected to be reached on this movement.

ZINC

Although the advance in the pound sterling has practically eliminated the possibility of imports from England, there now hang over the market imports of German zinc. This is a serious matter in view of the present state of the market. While it is not believed that the supply of such zinc can be large, it is now large enough to be a big factor. It is reported that 10,000 tons has been contracted for delivery in this country and that 2500 tons of this is known to have been sold at around 5.30 to 5.50c., seaboard. The fact that zinc can be made in Germany from German ore and shipped here at around 3c. per pound, seaboard, duty paid, is the serious phase. In Eastern markets there is already competition from this source but it hardly extends to Pittsburgh and even in the East some consumers will not use it. With the market as dull as it is, it is an important factor. Prime Western in the absence of demand of any consequence has fallen to 5c., St. Louis, or 5.50c., New York, with the imported metal available at 5.25c., seaboard, though actual information about this is hard to get.

ANTIMONY

Wholesale lots for early delivery are lower at 5.25c., New York, duty paid, largely because of the decline in silver to new low levels recently.

ALUMINUM

The virgin metal, 98 to 99% pure, is quoted by the leading interest in wholesale lots for early delivery at 28c. f.o.b. producer's plant with the same grade from other sellers available at 24 to 25c., New York.

ORES

Tungsten: There is very little, if any, business, the market apparently waiting for a decision on the tariff question which seems hardly likely to mature at this session. Holders ask \$3 per unit for Chinese ore.

Molybdenum: The market is inactive with quotations nominal at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: There is no business. Quotations are nominal at 35 to 40c. per unit, seaboard, for high-grade foreign ore.

Manganese-Iron Alloys: Ferro-manganese is in light demand at \$100, seaboard, for the British and \$105, delivered, for the American alloy. Spiegeleisen is inactive at \$40 to \$45, furnace.

T. A. RICKARD, Editor

UNDER 'Discussion' we publish a letter from Mr. W. J. Loring, the president of the American Mining Congress, on the McFadden bill, the purpose of which is to assist the gold-mining industry by levying an excise of \$10 per ounce on all gold used in manufacture and to pay the \$10 thus collected to the producers of new gold. Our own doubts as to the wisdom of this proposed law have not been removed, much as we would welcome anything likely to help the gold miner, but we are pleased to publish Mr. Loring's letter, which is all the more interesting because it was not intended for publication. As for the McFadden bill, we have said enough about it.

OUR contemporary at Spokane, 'Northwest Mining Truth', has been a consistent foe to the smelter trust and would therefore be expected naturally to chuckle over the attack made by Mr. Karl Eilers on the Guggenheims, but we think the editorial comment appearing in its issue of February 2 is unfair to the 'Engineering and Mining Journal' in so far as it describes a recent editorial on the subject by our New York contemporary as "the most pitiful exhibition of toadyism", "abject fawning", and a "defence of those who have broken faith with the public". This seems to us an unjustifiable description of the humorous article on the A. S. & R. company's troubles. We have taken them rather seriously ourselves, but we know of no justification for so bitter an onslaught upon "the few kind words that the 'Engineering and Mining Journal' has handed them [the Guggenheims] on its knees". Our contemporary in New York owes no fealty to those "who have milked dry the largest concern of its kind in the history of mining", as the Spokane paper characterizes them, but it does show the influence of propinquity and appears unable to understand how important and serious the subject is to those in the West who produce ore that has to go for treatment to the custom smelters. To them the Eilers-Guggenheim controversy is tremendously suggestive and to them it makes a great difference as to who is to control, and what policies are to control, the American Smelting & Refining Company.

MINING companies that tap subterranean water-channels in driving adits or tunnels can establish no claim to the resulting flow of water, according to a decree rendered by the U. S. Circuit Court of Appeals at St. Louis on February 5, in the litigation between the Snake

Creek Mining & Tunnel Company and the Midway Irrigation Company. The finding of this Court reverses the decision of Judge Tillman D. Johnson of the District Court of Utah, wherein the Snake Creek company, now merged with the Judge Mining & Smelting Company of Park City, was awarded the right to the water after establishing the contention that it was 'percolating'. The facts in the case were reviewed in our issue of October 30, 1920. The diversion of some 14 second-feet of water, which flowed out of a long adit driven by the Snake Creek company, rendered worthless some 1500 acres of highly productive farm-land. This latest decision guarantees the irrigation company title to all the water flowing from the adit, and enjoins the mining company perpetually from asserting any claim to it. We wonder if the Judge company is to be compelled to pump the water back again, up the canyon, or if it will be forced to bulkhead the adit and thereby revert the flow to its original channel. It will be interesting to see the full text of the decree, and also to learn whether an appeal will be taken to the Supreme Court. The decision is especially important to mining companies owning property in the neighborhood of streams that supply water for irrigation.

PROFUSE printing is one of the weaknesses of our day. A select committee has been investigating the printing and stationery expenditures of the British government, with the result that it reports a total annual cost of £6,000,000, as compared with £1,200,000 before the War. "A large part of this heavy increase in expenditure", says the committee, "must be set down to the propagandist zeal of various departments, which employ numbers of journalists and others to advertise their activities." This might easily have emanated from an investigating committee at Washington, where an orgy of printing and circularizing has been one of the sequelae of war activities. It continues, as we know by the large amount of paper that comes to us daily and that we rescue from waste by writing on the unspoiled back. To "employ numbers of journalists" is a venial sin, but to employ "others", presumably also in large numbers, is a crime; and together the performance is wasting an enormous tonnage of paper at a time when that commodity is profitteeringly expensive. Apart from this phase of the matter, it is highly undesirable that those in office should use the public money—the taxpayers'

tribute—to aggrandize themselves by their propaganda. The heads of Departments at Washington did it lavishly and unblushingly, even to the promotion of their candidacy for the Presidential nomination. It is hardly surprising that some of the lesser fry did it impudently. Whatever excuse for it may have been found at a critical period when it was necessary to mobilize the national sentiment in behalf of the whole-hearted waging of war, there is no excuse now. Thrift should begin at Washington, and it might well begin in the saving of paper, printing, and postage.

SO the financing of copper exports proves true, and we are glad to record the fact. A powerful syndicate of bankers has issued \$40,000,000 of 8% gold notes in behalf of the Copper Export Association, which includes most of the principal copper-mining companies and represents 75% of the copper production in this country. These notes mature in periods of one to four years and are secured by 400 million pounds of copper; the time for which they run will suffice for the marketing of the metal abroad in an orderly way and will relieve the producers of the financial burden of carrying the large surplus that has been menacing the market. The present rate of production is below the rate of deliveries of copper in 1919 and 1920, and the 400 million pounds, thus to be liquidated, represents an amount equivalent to only three-fourths of the export trade done by this country last year, so the market should experience great relief at once. The successful flotation of this loan will permit the companies to dispose of their accumulation of metal and will facilitate further development of their mines in anticipation of the time when trade with Europe regains its normal status. The companies participating are the Phelps Dodge Corporation, American Smelting & Refining, Calumet & Hecla, Utah Copper, Chile, Kennecott, Braden, Ray Consolidated, Nevada Consolidated, Inspiration, Greene-Canaan, New Cornelia, North Butte, and Utah Consolidated. This association agrees that one-third of its monthly shipments abroad shall be withdrawn from the trustees for the syndicate and that 12½ cents per pound shall be paid into his hands, either in cash or notes, for all such copper thus withdrawn. It is claimed that arrangements have been made for the transfer of large quantities of the metal to European purchasers. Altogether the event is one of great importance and of good augury to the mining industry of the United States.

THE contention that 'the shoemaker should stick to his last' is losing force. More work and work of a more varied character can be done during man's allotted span because of greater facilities and the elimination of waste. There is also a sense of invigoration in the tackling of something new, and this is an asset to the individual who, realizing that his actions are under the greater scrutiny, makes an unusual effort and often succeeds remarkably well. A short while ago a concern in the East advertised for a business-man to fill a position requiring a considerable amount of analytical and con-

structive ability. "What experience have you had in this particular field," he was asked. "None," was the reply, "and that is precisely why I consider I am suited. I have proved my capability in other work. I shall look upon every problem here from a fresh and unbiased viewpoint. If you care to make the experiment, I feel sure that I can make good." And he did. Capable mining engineers, too, usually find their feet when given responsibility in other branches of work, although many well-managed corporations do not realize their ability to extend operations into other fields of endeavor. We were particularly impressed recently to see the highly efficient way in which the management at the mining camp of Cerro de Pasco, Peru, was conducting a furniture factory, provided with the most modern equipment and labor-saving devices. The unskilled Indian, of low earning capacity under ordinary conditions, was becoming highly proficient; and the 'mission' furniture produced, although plain and serviceable as befitting employees' houses in a mining camp, compared favorably with the products of high-grade American factories. We came to the conclusion that, if considered worth-while, the Cerro de Pasco Copper Corporation could without difficulty capture a large proportion of the furniture business in Peru, as well as in adjoining countries. Not only was the factory being run on efficient and economical lines, but it was obvious that no interference was caused with regular routine mining work, an evidence of the fact that the entire operations were under the control of a capable executive. Good organization permits successful expansion; and it is no longer true that *ne sutor supra crepidam* when events are proving that his experience and the added ability gained by experience are sufficient to justifying him in seeking 'pastures new' whenever there is good prospect of success. We are interested in the report that the Alaska Gold Mines Company is planning to convert some of its mills and to utilize some of the available water-power for the production of wood-pulp. Spruce forests adjoin some of the properties belonging to the company, and the adaptation of a considerable part of the equipment on hand may be feasible. The controlling engineers are capable, and a change of luck in the fortunes of the company would be well deserved.

MERE smallness is a quality not to be despised; most things were once small. Mines and mining districts, like everything else, have humble beginnings. Every producing mine was once a prospect; courage, energy, and time have been required to make its exploitation a success; and generally there have been sceptics who ridiculed the possibility of developing a profitable enterprise. It must be confessed that the consistent pessimist was right more often than he was wrong for the reason that most prospects prove to be worthless or nearly so; only one in a thousand grows to be a real mine. One of the old 'camps' to awaken to new life recently is Cooke City, Montana, situated some 56 miles east of Gardiner, the gateway to the Yellowstone National Park. The inaccessibility of the district has always been a serious drawback, but recently the Western Smelting & Power

Company, controlled by Seattle mining men, has undertaken the exploitation of the immense deposits of copper-silver-gold ore of which Henderson mountain is said to be composed. The company has built a hydro-electric power-plant, a transmission-line, and some 50 miles of road; a series of adits has been driven into the mountain, and a small copper smelter will be ready for operation within four months. The investment already made is said to exceed half a million dollars. An important factor in the progress thus far made is the modern motor-truck. The road between Gardner and Cooke City has been put in good shape and the round trip with a full load can be made easily in a day. One engineer estimates 1,110,000 tons of ore worth \$46.34 per ton as being an "insignificant fraction" of the total ore-reserves; the same gentleman declares that he is not exaggerating when he says that "the Cooke City district far exceeds the wealth of Butte". This is large talk about what is, so far, a small mine; it shakes one's faith in the credibility of the writer. We know, however, that some conservative engineers have been favorably impressed with the district, and we feel justified in predicting the probability of a prosperous future for Cooke City, even though the well-known riches of Anaconda hill may not be so eclipsed as to sink into insignificance.

MR. C. M. EYE'S article on 'Packing for Export', which appears on another page of this issue, indicates the importance of attention to matters that are often neglected by engineers, whose time is taken up later in attempting to remedy the troublesome conditions arising from such neglect. Indifferent and careless packing and marking leads to loss and breakage, endless correspondence and delays, the waste of good talent needed to effect repairs, and the deflection of much business energy. Mr. Eye, whose successful work in the Philippines gives him the right to speak with authority on such matters, deserves credit for the example set and the impression given that whatever is worth doing at all is worth doing well. It is largely through the avoiding of waste of time and labor—a waste resulting from the necessity of having to pay continual attention to unimportant details—that the successful engineer achieves so much. Manufacturers and merchants in the United States are tardy in realizing the importance of such details; but unless they are prepared to study the question there will be constant disappointment abroad and loss of custom at home. We use the word 'study' advisedly, for we remember an instance in which the exporting firm had fully realized the necessity for careful packing before shipment, even to the sealing of the package in a case with soldered joints; for the apparatus, of somewhat intricate design and workmanship, had to pass through the tropics before reaching its destination. They used care, but no thought. The sealed case kept out the moisture of the tropics but it did not exclude the heat. The apparatus was packed on a damp day and in a damp warehouse, the humid atmosphere was sealed in, and the heat of the tropics, in conjunction with the trapped moisture,

damaged the apparatus to an irremediable extent. Such an example as this indicates that no detail of packing or marking is unworthy of attention by manufacturers anxious to receive encouragement in the form of repeat orders from overseas; and for this reason we welcome Mr. Eye's contribution as indicative of a desire on the part of engineers to co-operate with American industry, as well as to facilitate mining expansion in tropical countries.

Colorado School of Mines

Friends of the Colorado School of Mines—and it has many—will regret to learn of the further development of unsatisfactory conditions. These are emphasized by the resignation of Mr. C. Erb Wuensch as editor of the 'Colorado School of Mines Magazine', a monthly periodical conducted under the auspices of the Alumni Association. Mr. Wuensch has aroused the antagonism of Dr. Victor C. Alderson, the president of the School, and the dislike of the trustees, by his criticism of them and by his publication of the condemnatory report, on them and their administration, by a select committee of the American Association of University Professors, to which we referred at some length in our issue of September 11, 1920. This rumpus was inevitable, for the tone of Mr. Wuensch's remarks in the December issue of the Magazine left no doubt as to his hostility to the powers that be; he might, we think, have been less violent in his language, which was such as to make it certain that one of the contending parties would have to quit the field. In the January issue of the Magazine we are shown the correspondence in the case, as well as a number of letters from alumni. It is evident that the old students of the School are not in agreement as to the proper course to pursue, and their position is rendered all the more difficult by the fact that the president of the Board of Trustees is an alumnus who seems to be working with Dr. Alderson and the other trustees. The letters published by Mr. Wuensch indicate that many of the old students dislike intensely the idea of placing the School under the regency of the State University, which centres at Boulder, and that the fear of this subordination of their alma mater causes them to deprecate the attacks made upon Dr. Alderson and the trustees. Of course, as the Secretary of the Alumni Association says, the School belongs primarily to the citizens of Colorado, not to the alumni only; unfortunately the people of the State are not correctly informed concerning the facts, because, among other factors, one of the trustees is the mining reporter on the principal newspaper of Denver and moreover the selection of the trustees is in the hands of the Governor, who, of course, plays small politics. Just now the School is flourishing, in point of the number in attendance, as are all the other mining schools of the country, this being one of the after-effects of the War period, so that the dissensions among its friends appear to have had no adverse effect. The faculty is in a continual state of flux, three having resigned since July and two others being about to do so. Indeed, according to Mr. Wuensch, the oldest

member of the present faculty has held office for less than four years. As our readers know, we sympathize with those who deprecate Dr. Alderson's methods and more with those who consider the trustees insufferable, particularly the older members of the board, who are entirely unfit to guide the destinies of an educational institution, but we conclude that not much can be done, as it now seems apparent the alumni are unable to agree upon a plan of campaign. To us it appears reasonable and logical that the School of Mines should be a part of the State University system, particularly as its present control has proved so inefficient, for the change can be brought about without moving the actual site of the School from Golden to Boulder. The chief lesson of the scandal is the need for rescuing the educational institutions of a State from the hands of the politicians, and that can be done only by direct election of the trustees by the people or, better, by selecting the majority of the trustees ex officio from among the leaders of the mining profession in the State, as we suggested last September.

Institute Membership and Professional Status

We publish two letters protesting politely against our assumption that a mining engineer is not in good standing if he be not a member of the national engineering society. Mr. P. B. McDonald insists that membership is a matter of personal choice, like joining any other fraternity or mutual-benefit organization, but we demur to this view because our Institute aims to be, and comes near to being, completely representative of all American mining engineers of good character and proved ability. The longer letter from Mr. F. C. Smith calls for fuller comment. We join with him in his kindly reference to Professor Pettee, whose memory we shall never cease to honor and to whom many volumes of Transactions owe more than is generally recognized by our members. Mr. Smith tells us why he resigned, and we can go part of the way toward understanding his reason for doing so, but it did not occur to us or to others at the time that it was necessary to resign just because things went wrong temporarily. Such troubles befall even the best regulated organizations; and when they happen it is best, not to withdraw, but to come forward with constructive criticism. Mr. Smith questions the selectness of the Institute's membership and asks how many hold a college degree of mining engineering. We are unable to answer his question, but we would hazard the guess that 25% of the members are graduates in mining engineering and 40% in all have degrees in mining or metallurgy; also that 70% have degrees of some kind. Undoubtedly the higher requirements and the greater care taken in electing new members during recent years have improved the quality of the membership in so far as it can be assured by artificial criteria. However, the difference of numbers between the Institute and the Mining and Metallurgical Society remains a standing commentary, if not a standing joke, on this phase of the problem, for the exclusive society has 300 members and the inclusive one has 9500.

Mr. Smith suggests that membership in the Institution of Mining and Metallurgy, which represents the British mining engineering profession, means more than a like status in our own Institute. To this we would say that the British organization includes 2400 men, of whom only 950 are full members, the others being associates and students. Of the members, 91 are resident in the United States, and it must be conceded that they constitute a group of widely traveled men, most of whom enjoy an international reputation, or, to be more precise, they are well known both in New York and London. The membership of scarcely one thousand in the London society does represent a selection of men so qualified by training, experience, and character as to accord them a definite status in the profession. The mining activities of the British dominions centre in London to such a degree that it is easier to scrutinize the eligibility of those proposed for membership than is practicable in our own country, in which a number of mining and financial centres serve as headquarters for the profession. To be a British mining engineer and not to be a member of the Institution does indicate a lack of status. So definite an inference cannot be drawn regarding an American mining engineer whose name does not appear on the roster of our Institute, but even after allowing for those who have been so disgruntled or irritated by minor happenings as either to resign or to decline a membership for which they were eligible, and making allowance for the type of man who is non-gregarious and non-coöperative, and therefore remains detached, it still is true in a broad way that an American mining engineer in good standing is usually a member of the Institute, and therefore the converse generally holds true: if he be not a member he is probably, although not certainly, in poor standing in his profession. Any individual, however, such as Mr. McDonald or Mr. Smith, may, by known character and proved ability, be so well recognized by the members of his profession as to render his non-membership of no great consequence to himself; but we venture to say that if a comparatively unknown man, whose name is not to be found on the roll of the Institute, comes into the limelight of newspaper publicity as an American mining engineer, one is fully warranted in doubting his status in the profession; although, in this case also, later information may prove that his work and achievements are such as to remove any reasonable doubt concerning his qualifications. One word more: The claim to membership in a professional society may mislead, for the reason that a man's character and ability change during the course of his life. An engineer who is fit and competent at 35 may be unfit and incompetent at 50; an unfortunate marriage or the acquirement of bad habits may undermine both the character and ability of a man as he grows older. Many members would fail of re-election ten or twenty years after joining an Institute or Institution if they were obliged to undergo an examination. On the other hand, young men black-balled or otherwise excluded at one stage of their lives may so improve in character and so gain in ability as to be eligible later on. "Who hath

made thee a judge over us?" Every effort to classify men is open to criticism because none of us can read the motives of others, nor estimate confidently their moral qualities. Whited sepulchres flourish in positions of honor, and the victims of circumstance are buried in ignominy. It is a difficult and an ungracious task to appraise professional men, yet it has to be done for the sake of solidarity on the one hand and the protection of the public on the other. If the Institute is not representative in the eyes of Messrs. McDonald and Smith, the best thing they can do is to join it and make it just that much more nearly representative.

The Domestic and Foreign Supply of Nitrate

The amended nitrate bill, which embodies proposals brought forward by the War Department, passed the Senate on January 14. The original measure, which proposed the creation of a Federal corporation for the purpose of operating plants to manufacture nitrogen products, is of moment to those interested in national defence and economy or in professional or trade expansion in South America, and has been under discussion for several weeks. The amended bill may be classed among parliamentary futilities; for the financial conditions imposed upon the new corporation are such that a successful outcome is impossible without the adoption of a paternalistic policy of protection that would abnormally increase the cost of nitrogen products, both to the War Department and to agriculturists. The crux of the question is seen in the requirement that if at the end of any fiscal year the corporation has not earned sufficient to meet the interest payment on bonds, it shall cease operations until authorized by Congress to resume. Such a stipulation is an absurdity in the case of an industry that has hardly passed the experimental stage, and in connection with which there is no evidence to indicate that competition along commercial lines with products now on the market could possibly be successful. The profit requirement, as stipulated in the amended bill, will serve only to kill initiative along one of the most important avenues of research, of vital importance to national defence; for chemists and engineers of reputation will hesitate before they associate themselves with a venture of doubtful outcome—one that is, in the opinion of many, foredoomed to failure. And failure is inevitable unless steps are taken to increase the selling price of nitrate products by the establishment of a protective tariff against importations from Chile. And in view of the necessity for a decrease rather than an increase in the price of a commodity so vitally connected with the cost of living, such an action would be deplorable, and would place the United States at a serious disadvantage.

So far as competition with the Chilean product is concerned, the following considerations deserve attention: The imported article is more suitable, for both munition and agricultural purposes, than any of the synthetic compounds to be manufactured at Muscle Shoals. Chile now reaps an annual income of about \$40,000,000 from the

export-tax on nitrate. With the approach of any prospect of commercial rivalry from the competition of a synthetic product, this export-tax would be reduced *poco poco*, and so the cost of the natural product would be cheapened to the ultimate consumer, who now pays the tax, though indirectly. Whatever happened, the natural nitrate industry would be held intact, and, if necessary, revenue would be gathered from other sources. But Chileans are far from feeling discouraged at the outlook, because their country holds the world's monopoly of nitrate in commercial deposits. During the War the bogey of synthetic nitrate was used to frighten them, but, as nothing eventuated after the Armistice, they now know that the scare had no foundation; and the Chilean industry is in a stronger position than ever. Further, recent developments of a technical character have demonstrated that, provided scientific and large-scale methods of operation are adopted, the cost of production will be reduced considerably in the near future, and immense quantities of low-grade caliche and residue, previously considered valueless, will be available for profitable extraction and treatment. Improvements in technique and a more intelligent management of technical operations on the Chilean pampa are inevitable. American engineers as yet have interested themselves almost entirely in the commercial aspect of the problem: the sale of plant equipment to the owners of oficinas, and the reaping of commissions. Large-scale operation has been pooh-poohed and discouraged as impracticable and against the laws of the country—as if Chile would put obstacles in the way of a progress that would increase enormously the value of the nitrate pampa to the nation and cheapen the production of crops throughout the world! The real reason for the objection lay in the fact that large-scale operation would preclude the possibility of the adoption of the complicated processes and the use of the expensive equipment that have been advocated by salesmen-engineers, who seem to dominate the industry as far as technical modification of procedure is concerned.

A propaganda was set in motion in the United States during the War, which hinted that attention paid to the technique of the Chilean nitrate industry would be looked upon in some quarters as an evidence of lack of patriotism, and indicative of a refusal to support loyally the efforts of American engineers and chemists to produce a synthetic substitute. One result of cumulative discouragement and lack of initiative is that, according to the last issue of 'Mineral Industry', only 2.52% of the total output of nitrate was obtained from oficinas belonging to American owners, whereas British interests controlled 37.76%. The Jugo-Slavs, recognized in South America for their acumen and business ability, are steadily increasing their holdings in the Antofagasta district, and before long will control a large proportion of the industry in that part of Chile. There is an immense field for independent American engineers—for men who are disinterested in the sale of patented machines, who realize the importance of a clear understanding of the fundamental principles in the operation of chemical processes,

and who have ideas big enough to still the croakings of the local pessimists who are content to point to the failure of unsuitable and complicated equipment as the reason for lack of initiative to think beyond early Victorian technical methods. However suitable these may have been fifty years ago, they are certain to be displaced by modern ideas, permitting large-scale and economical operation; for the Chilean nitrate industry is not likely to remain indefinitely a single exception to the spirit of advance. The price of nitrate nominally is controlled by an association consisting of Chilean and foreign owners. The absurdity of this method of price control is seen in the fact that during November the actual market for nitrate was about 13s. 6d. per quintal (about 100 pounds), whereas the price set by the association was about 17s. 3d. The few American companies operating in Chile, thanks to their subordination to American anti-trust laws, are not members of the association. Further interest in the industry by American corporations and individuals would tend to abolish or minimize the evils caused by the restriction of sales of Chilean nitrate owing to the prohibitive price set by the association. With regard to possible competition with synthetic products, it must be admitted that Chile will hold the field for the cheap production of nitrate for some centuries to come. On the other hand, and to meet present and future military requirements in the United States, it is obviously a sound policy to initiate work that will obviate dependence on Chile in time of war. The active co-operation of the United States in the winning of the Great War would have been rendered impossible without the availability of almost unlimited supplies of Chilean nitrate; and these supplies were obtained only by the assistance of the British, who hold a large share, as already mentioned, in the Chilean nitrate industry. Had a certain hint made to a prominent naval official—that it was immaterial as to which nation the United States engaged in war, Great Britain or Germany—been taken seriously, the question would have arisen as to how the United States could obtain the necessary nitrate for the manufacture of explosives. And now the prospect of obtaining a supply of synthetic nitrogen products in the United States is still further pushed into the dim future by the action of Congress in insisting on the operation of the Air Nitrates Corporation as a commercial undertaking. Such a policy can do nothing to reduce dependence on Chileans, British, or, possibly, Jugo-Slavs, for the supply of nitrate in times of peace or war. A lesson can, however, be taken from Germany's attitude: Prior to 1914, immense plants were built, and processes perfected as far as was possible, with the help of the best scientific and technical skill available; but even with the comparative cheapness of operating conditions in Europe at that time it was obvious that the expenditures were solely in anticipation of a war-time necessity. The proof of this assertion is found in the fact that Germany was largely interested in the Chilean deposits before the War, and imported vast quantities of the natural product so long as it was possible to do so. The perspicacity of the Germans in realizing at

an early date the small commercial value of their synthetic nitrate plants, and, in consequence, laying up large stocks of Chilean nitrate, was a contributing cause to the success of the stubborn defence and bold offence that characterized their military operations during the earlier years of the War. With the exhaustion of these stocks of natural nitrate and the enormous cost and great difficulty of manufacture of the synthetic product came a realization of impending disaster; and the difficulty of obtaining a sufficiency of nitrogen products at a moderate cost was doubtless a contributing cause to the signing of the Armistice. From these facts it would seem wise to deduce that, so long as ships are available to carry the product, the nitrate from the Chilean pampa must inevitably hold the field against any synthetic products, especially in view of the imminence of the introduction of large-scale operation and more efficient beneficiation of the caliche, both of which will, naturally, have the whole-hearted co-operation of the Chilean government. There is no sense in the United States entering into competition with Chile at the present time in the matter of nitrate. There is no sense in killing the domestic synthetic nitrate industry at its birth by imposing conditions that must inevitably lead to disheartenment and failure. A vast amount of capital must be put into research and operation before a steady output of a suitable product can be assured. The undertaking must not be confused with a commercial business. With a realization of the facility with which Chile can reduce the cost to the consumer—by lopping the export-tax and by the adoption of improved technical methods—no individual or group of individuals can be expected to enter the synthetic nitrate business with any hope of meeting expenses, much less operating at a profit. The undertaking must be considered as one primarily for the purpose of provision in the event of war and the cutting-off of supplies from Chile. It must be financed, and financed liberally, by the Government. It must be operated experimentally until efficient results are secured; and during such time the work must not be hampered by considerations of profit or loss. Unless the matter is treated as a scientific investigation there is little hope of ultimate success; and it is only under such conditions that the best chemical and engineering skill of the United States will be available for the solution of a problem which it is admitted on all sides is of vital importance to the country. In the meantime it is to be hoped that American engineers and financiers will take an increasing interest in Chilean nitrate, ignoring any absurd imputation of disloyalty to the United States in furthering an industry that, unfortunately for us, happens to be monopolized by a foreign country, with which we are and expect to remain on the most friendly of terms. We must realize the economic importance of an interest in that industry in proportion to our needs. The longer the question is shelved the greater will be the opportunity for others to study the question and to act in a manner commensurate with the vast possibilities of success, in the technical as well as in the commercial aspect.

DISCUSSION

Status as a Mining Engineer

The Editor:

Sir—In your issue of January 15, under 'The Vanderlip Concession', you make the somewhat broad assertion that "most of the few engineers conspicuous by their detachment from the national organization—the American Institute of Mining and Metallurgical Engineers—are what we call cranks; therefore, if a mining engineer is not a member of the Institute, it is fair to say that he is not in good standing as an American mining engineer".

This airy persiflage may have been written for the purpose of "getting a rise" out of the alleged cranks, or possibly with the purpose of increasing Institute membership as an economic measure—the reduction of the present \$27 per capita tax; however, as it is not generally known that the profession of mining engineering has been unionized to the extent of black-listing detachees from the Institute, or to the extent of taxing engineers with advertising costs of which they may not discern either the need or the value, it is barely possible that courtesy demands some further enlightenment, to the end that those unfortunates beyond the pale may, possibly, see the error of their ways.

The writer became a member of the Institute a good many years ago—in 1884, if memory serves—under the kindly introduction of the late W. H. Pettee, Professor of Mining in the University of Michigan, who for many years read all of the manuscripts and corrected all of the proofs for the Transactions; going over every calculation and formula with the microscopic care so characteristic of all his work. Professor Pettee had been an associate of Dr. Raymond, the father of the Institute, at the Freiberg mining-school, and these men, with others of similar character and worth, seemed to set up certain standards that rendered membership in the A. I. M. E. a valuable and agreeable association, while they lent the Institute a true dignity, which, to some extent, has perhaps passed away with them. The membership was continued for something like 25 years, when occurred what seemed to be a somewhat disgraceful squabble over the election of officers; then went glimmering (if your dictum is correct) all remnants of "good standing as an American engineer", for the writer experienced what may be termed a sense of repletion, and resigned; a momentous act, which, if the truth must be told, has been equally innocuous to both the Institute and himself.

Readily admitting that membership in the A. I. M. & M. E. constitutes association with much of the best in engineering circles, and that its list of members consti-

tutes a convenient directory (to some such an extent as the lists of engineers advertised in the 'Mining and Scientific Press' and the 'Engineering & Mining Journal') there yet seems to be some slight question as to just what definite ability, or character, or education is in any way established by such membership; such, for instance, as rather particularly attends membership in the Institution of Mining and Metallurgy of London. Without exact knowledge of the Institute's membership requirements today, it is not so very long ago when practically anyone (with or without knowledge of mining engineering) might become a member by proper introduction and payments of fees—a condition somewhat liable to upset any very definite status for its members. To the same extent that the precise educational requirements of certain foreign schools predicate definite knowledge for their graduates (Swiss medical schools, for instance), it is not to be denied that an E. M. degree from a sound college or university might be considered as the only proper basis for our use of the title of Mining Engineer. We all recognize ability and efficiency in many mine-operators or engineers who have been, in a way, self-educated, and who have never perhaps entered the doors of a college; while we are also familiar with a few cases in which graduate mining engineers have most distressingly lacked the practical training so desirable and necessary. But, fully recognizing these conditions, abundant reasons still remain whereby the unaccredited use of the title of Mining Engineer maintains quite the impropriety of similar misappropriation in other professions; and it might be interesting to know just what proportion of the members of the Institute actually hold the degree of E. M. Possibly you, sir, can supply the information.

Chloride, Arizona, January 25.

F. C. SMITH.

The McFadden Bill

The Editor:

Sir—I need not call your attention to the deplorable condition of the gold-mining industry in the United States, and more particularly, may I say, in California. This deplorable condition has been brought about by causes over which we, as gold-producers, have had no control, but we do feel, as gold-producers, that we have some control, or at least we should exert ourselves toward attempting to control our future destiny and before it is too late to save the gold-mining industry, not, as some would say, from total extinction, because that would be impossible, but from gradually decreasing until it will take a very minor place in comparison with the impor-

tant position it had held up to the beginning of the War.

You know the intention of the McFadden Bill and I know that you have not been altogether in favor of this measure, which I somewhat regret, but it would appear to me that we as gold-producers, and you, presumably an exponent of the mining cause, should pull together in obtaining such relief as the McFadden Bill might eventually give us, or at least until some other measure is brought forward that is more suitable in the opinion of the majority than the McFadden Bill.

It appears to me that we should not overlook the fact, which government records substantiate, that the production of gold is dropping off each year and unless something is done, and done almost immediately, it will be too late to save the industry from drifting into a condition that I am very much afraid it will never recover from.

The idea that the gold-producers will be compensated in the end, for the losses made during the period when high prices have prevailed, by enjoying normal conditions in the future appears to me to be about the worst argument that can be put forward. What are we going to do with the large low-grade gold mines in the United States, such as the Homestake? This mine, when costs became excessive, ceased breaking ore and is drawing its shrinkage-stopes, with the result that when the broken ore has all been drawn out of the shrinkage-stopes the mine will be ruined, because the backs cannot be reached and therefore no milling ore can be broken in the mine for that reason. It is probably too late at the present time to save certain sections of the Homestake. I refer to this as an example of what is going on all over the country. Worse still, mines now being operated are selectively stoping the best ore, leaving what before the War would have been highly payable. Those low-grade sections have already been developed, the equipment has already been paid for, and it would appear to me to be a great pity to allow the millions of ounces of gold contained in the low-grade ore that has been developed in our country to remain unused, practically lost forever.

It is the intention of the American Mining Congress to do everything within its power to bring about the passage of the McFadden Bill and thereby save the gold-mining industry from almost total extinction, and to at the same time produce gold which is necessary to maintain the financial integrity of the nation.

You may take issue with me upon the small part that the production of gold in the United States plays in maintaining the integrity of the nation, but however small it might be, it is certainly a step in the right direction and, after all, we work upon a gold standard and whatever gold is produced is certainly assisting to maintain that standard. If every country in the world was subjected to a depleted gold production we would soon find ourselves in a very deplorable condition.

It is interesting to know that in California alone from 1848 to 1920 the enormous sum of \$1,720,496,203 was produced, which in itself is within shooting distance of the normal gold reserve of the United States.

It is proposed to call a meeting, the date of which you

will be informed of later, at which I hope to see the faces of not only the gold-producers of California, but other business men who are benefited directly and indirectly by the gold-mining industry of this State, and I further hope that we will receive the financial support of these good people, which is absolutely a necessity in order to carry through this campaign, which we have begun and which we intend to stimulate with all the power that we possibly can bring to bear upon the subject.

It is my sincere wish that you give this matter your most serious consideration and assist us as far as you possibly can in the direction referred to above.

In my opinion, this is no time for important business men in this State to refuse to co-operate in trying to save an industry that means so much good to the State and Nation and which, as a matter of fact, laid the foundation for the wealth of our great State, and that foundation was the "yellow metal".

San Francisco, February 1.

W. J. LORING.

[This letter was not intended for publication, but it is published by Mr. Loring's permission, at our request.—EDITOR.]

Producer-Gas

The Editor:

Sir—In your issue of January 8 of this year, I note a letter by Mr. M. W. von Bernewitz on the subject of producer-gas, and, as this subject has received a great deal of my attention for the past fifteen years, perhaps additional light on the subject may be of interest.

Mr. von Bernewitz's statement that the number of producer plants in this country is small as compared with the European field, leads one to the impression that the state of the art in this country is behind that of European factories. The real reasons that influence the very slight progress in producer work in this country are, first, abundance of cheap coal suitable for steam purposes, and, second, the high cost of labor. In Europe, conditions are exactly the reverse. There we find an abundance of cheap labor, while the price of coal is at a high figure. In the course of my work, I have had occasion to operate European producers, such as the Mond, Koerting, Crossley, etc., in this country, and I have found, without an exception, that they have made a poor showing as compared to our native product, this being entirely due to the fact that they are not designed to operate on what we consider low-grade fuels. By low-grade fuels, I am referring only to fuels that are considered of low grade in gas-producer practice, which take into account neither the heat-units nor the market-value but entail such things as caking, fusible ash, high percentage of non-condensable tar, and also structural differences that interfere with the operation of gas-making.

While it is undoubtedly true that in Europe gas-producers are operating successfully on so-called low-grade fuel, these low-grade fuels are practically free from the elements referred to, it being far more important in gas to have a free-burning non-caking fuel than to have one high in heat-units. For example, I have operated

successfully a plant on No. 1 Buckwheat coal, averaging 18% ash, for 24 hours per day, for 11 consecutive years, the sole shut-down during that period being for a new set of brick linings. On the other hand, the endeavor to operate on our caking bituminous fuel, has invariably resulted in unsatisfactory performances. A large measure of the success in Europe is due to the fact that a careful selection is made of the fuel so as to segregate those suitable in character, regardless of the price, for gas-making; and once a plant has shown successful operation on a particular fuel or mixture of fuels, henceforth that exact combination of fuel is carefully provided for.

While it is true that a gas-producer can handle almost any combustible and make gas therefrom, it is also true that only certain fuels, having the proper characteristics, are found capable of manufacturing a uniform yield of gas such as required for the operation of gas-engines. Just as long as conditions exist in this country whereby it costs so much more to select, size, and grade our fuels, especially for a given plant, a practice due to high-labor costs and the type of available labor for the operation of plants which is at the present time of the lowest possible order, so long will it be impossible for this country to produce a showing in any way comparable to European practice, as to volume.

On the other hand, it is interesting to note that many plants in United States are operated on fuel that could not be handled by any of the European producers. The high percentage of fusible ash in our American anthracite makes it necessary to rate down the size of producers to keep the coal between 8 and 10 lb. of coal per square foot of grate-surface per hour, whereas with Welsh anthracite, 30 lb. per hour can be successfully gasified; and it was due to this large variation in capacity and to the fact that all the European producers shipped to this country failed to develop the rated capacity, that the producer business was given a black eye at its inception, inasmuch as the first plants installed were of foreign make. Any one of these errors as to ratings of European producers would be disastrous to the trade in this country, but the condition was further aggravated by the American manufacturing companies' total ignorance of the business, following blindly the dimensions taken from European practice.

Finally, in addition to the above-mentioned handicaps, the horse-power installation costs of gas-engines compares so unfavorably with the price of steam-engines, that manufacturers do not care to entertain the additional investment of a gas plant, even in the face of the possible economy obtainable thereby.

European gas-producers are undoubtedly to be congratulated on the feats they have performed with their plants, but they are by no means as remarkable as would be imagined from records that have reached this country. For example, the central station at Tours, France, which is reputed to be operating on saw-mill refuse, was found when inspected by myself, to consist of five producer-gas units, three of which were operating on saw-dust and small wood and the other two on high-grade anthracite.

The great variation in the quality of the gas made from the wood refuse was compensated by the fact that this gas went into a holder also supplied by the uniform gas generated from the anthracite plant, hence the resultant variation was within reasonable limits and enabled the operation of the plant. The amount of apparatus and equipment necessary to supply the gas at this plant, however, was fully three times as large and elaborate as would be considered by American industry, the producer-room being 165 ft. long by 60 ft. wide, all of which space was occupied by the producers, purifiers, scrubbers, etc., while the resultant horse-power generated was about 500.

This may be compared to an American manufacturing plant, the Horton Ice-Cream plant in New York, which had a producer-room 25 ft. by 30 ft., containing 750-hp. producers, which pulled a continuous load 24 hours per day, and there being no gas-holders to relieve the situation and to take care of any variation in quality of gas. Nevertheless, even with this rather remarkable showing, it is doubtful whether the owners of this plant would purchase a second gas-engine installation inasmuch as the labor charges and investment costs are so high compared with what could be obtained from a steam installation, equipped with automatic stokers, etc.

Generally speaking, therefore, it is not the difference in the state of the art in Europe and the United States that accounts for the comparatively small installation of gas plants in this country, but the difference can be ascribed to the high labor-costs and low fuel-costs, which to a large measure remove the incentive for using this type of installation.

Washington, January 27.

An International Association of Silver- Producers

The Editor:

Sir—Since the publication of my former communication, in your issue of December 18, that of Mr. Hugo W. Miller has appeared in the issue of January 8, and it seems that I have not been completely understood. An international association of silver-producers would not have the object expressed by Mr. Charles Butters, in your issue of May 31. Mr. Butters, it will be remembered, wished to have silver coins brought into general circulation in the United States, instead of paper.

My suggestion was not intended to apply to operators in the United States, as for the present these are quite contented, but to those in other countries, mainly Mexico and Canada. Nor can we think that an association of silver-producers would for one moment consider the possibility of introducing bi-metallic standards, as suggested by Mr. Miller. With the silver-producers the present is no time for the re-consideration of momentous political schemes, even if there were a chance of carrying them out. The producers, other than those of the United States, are in a sad plight, and all they wish is to get out of it.

The bad effect of fluctuations in the price of silver is

seen in India, by the growing preference for gold in place of silver. Such a preference formerly grew in Europe until the more valuable standard replaced the less valuable, the bi-metallic period being one of transition only.

It is perhaps not necessary to again state the most important part the producer should take in stabilizing the price of silver, but the possibility of his efforts in other directions may be considered. The history of silver shows that aggressive action on the part of the producer can materially increase the amount of this metal employed as a circulating medium. In the 16th century the silver of a rich mine at Joachimsthal, Bohemia, was mined by the owners into a coin, known as a 'Joachimsthaler', so as to pay wages and other mining expenses. The coin began to circulate freely in the surrounding German countries and its name was shortened to 'thaler', from which comes the English word 'dollar'. For similar reasons, Spanish coins made of Mexican silver were later put into circulation, and at one time were even recognized as common currency in England and all western Europe, as well as in the Americas, being commonly referred to in the English language as 'dollars'. Still later the Mexican trade dollar invaded the Orient. The process was automatic, because the governments concerned made good profits in coining the silver, even as the Mexican government is now doing.

The ultimate consequence of the present large-scale coinage of Mexican pesos will be the practical elimination of gold from Mexican currency (by Gresham's law). This, in turn, will affect the premium on gold in Mexico, so that gold mining will be benefited as well as silver mining. A still further coinage of the new peso would not so easily find its own way to Oriental countries, because Mexico is not now, as formerly, in the route of travel between Europe and the Orient. The migration could be facilitated, however, by an international association. The result would be better if the producers were to have a coin struck, similar in size and general appearance to the Mexican trade dollar, but having its name and silver content stamped on it in various languages. The Mexican trade dollar fixed the standard unit of silver coinage for several Oriental countries, and such a coin has easy access to commercial use.

One must not overlook the fact that Russia, Siberia, and other countries are overdoing the issue of paper money, and if silver is made available in quantity, by a proper organization, it might now be acceptable by those who have raw material for sale, and therefore by those commercial firms or associations who make trade with Russia their business.

What Mr. Butters says about silver advertising itself is very important, but one should popularize it in those parts of the world where there is reason for its demand, that is to say, where there is not confidence in a government's ability and good faith to redeem its paper. One may imagine that if the owners of the Joachimsthal mine had depended on the sale of silver bars, as we do now, they might have had to produce on a very limited scale. So might the Spaniards and later the Mexicans. Some-

one had to take the initiative and put silver in convenient form for circulation, then offering it for commodities to traders with a country where there is a lack of stable money.

BLAMEY STEVENS.

Triunfo, Baja California, Mexico, January 25.

Mining Engineers and the Institute

The Editor:

Sir—In your issue of January 15, in an editorial on Mr. Washington Vanderlip, you make the assertion that all mining engineers worthy of consideration belong to the Institute of Mining and Metallurgical Engineers. Those few who don't, you say, have some personal grievance against the honorable secretary or are simply cranks. Such a statement reminds me of the talk of a machinery salesman who implies magnificently, in his effort to impress you, that "of course everyone of any consequence uses our product".

As a matter of fact, I know dozens of mining engineers, of all degrees of importance, who do not belong to the Institute, and see no reason why they should join that body any more than they should join the Elks, or the Red Men, or the bald-headed league. Many mining engineers get enough technical reading-matter by subscribing to either or both of the mining engineering weeklies, and do not find the publications of the Institute especially interesting. The local meetings of the Institute are, of course, worth attending in some parts of the country, but in other parts, for various reasons, they are not.

The point I wish to make is that there are excellent reasons for many reputable mining engineers not being members of the Institute, and some of them, as Mr. Shockley suggested, have a considerable knowledge of mining.

P. B. McDONALD.

New York University, January 20.

THE currency throughout Chinese-controlled Manchuria, according to a consular report, is in the same unsatisfactory condition as in other parts of China, there being no standard coin nor any fixed rate between numerous moneys current. The value of each is determined from day to day according to credit of issuer, denomination, or the demand for it in the market. The ruble has depreciated the most, the Japanese yen alone maintaining really sound value. Currency of the following equivalent is negotiable: (1) Chinese currency—such silver as the sycee, one dollar, and subsidiary coins; copper in old cash, one-fiftieth and one one-hundredth of one-dollar coins; notes issued against new silver coins and old copper cash. (2) Of foreign currency—such silver as the old Japanese yen, Japanese subsidiary coins, Russian subsidiary coins, Hongkong dollar, and Mexican dollar; notes issued against such currency, consisting of silver-standard notes from the Yokohama Specie Bank and various foreign banks of Tientsin and Shanghai; gold-standard notes from the Bank of Chosen and Bank of Japan; and in normal times the Russian ruble notes.

A 250-KW. GENERATOR, WEIGHING FIVE TONS, AT THE TOP OF A MOUNTAIN, READY TO START DOWN

Packing for Export

By C. M. Eye

INTRODUCTION.—A local firm, advertisers in the 'Mining and Scientific Press', heads a recent circular on this subject with the statement: "We Know How to Pack for Export", and follows this with a quotation from the 'Literary Digest':

"In the last few years, the increased cost and shortage of proper wrapping and packing materials have induced many shippers to adopt a policy of unwise economy, whereby they use inferior packing not sufficiently substantial to withstand ordinary handling in travel."

Now, I am convinced that this firm, in common with many exporters in San Francisco, does know how to pack for export, and does pack as carefully as possible. In

consequence, they suffer very few breakages or losses, either in ocean transit or in delivery to the final destination, which may be some remote point in South America, in the interior of China, or in the Philippines. In order to ensure such safe delivery, not only is it necessary to observe certain well-developed rules having to do with the safe handling and storage of goods in the holds of ships (for most goods exported from here begin the journey by boat), but the conditions under which delivery is made in the foreign country must be known and met in due course.

Now, I am not posing as an expert in the art of packing, but I have received many thousands of dollars' worth

—AND ITS ARRIVAL AT THE BOTTOM, TWO DAYS LATER

of goods in localities many thousands of miles from here, and so I have had a chance to see the results of both good and bad packing. The proof of the pudding is in the eating, and I wish to say that it leaves a bitter taste to have some article, for which one has waited a long time and which is essential, either broken or missing because of lack of care in the original packing, or to receive a package of goods that has to be unpacked at seaboard and subjected to risks of breakage or loss of parts, because it is too large or too heavy to handle with the means at hand.

It is the business of the consignee, of course, to supply the necessary information as to how the goods are to be handled after landing, stating the allowable limits of weight and dimensions of any given package, the extent to which goods are to be protected from moisture, with full instructions as to marking, billing, etc. Then it is up to the exporter to comply with these limitations and instructions. Local conditions vary so greatly in different parts of the world that it is difficult to generalize, but the conditions governing shipment by sea are pretty well standardized. Let us try to follow the process through from start to finish:

SHAPE OF PACKAGE. There is no doubt that where conditions permit, the rectangular package (box or crate) best fits ocean shipment, and, as a rule, local conditions at the other end of the journey. During the War, the congestion and the lack of space led to the substitution of boxes for barrels. This not only economized space and saved money for the consignee by cutting down the cubic measurement for a given quantity of goods (for, as everybody should know, most ocean shipments are figured in the so-called cubic ton of 40 cu. ft. or the metric equivalent), but in most cases the change was also welcomed on account of the more convenient handling of boxes for local transportation. It seems to me that the use of barrels is only justified, outside the shipment of oils and other liquids, when some fragile article, such as a graphite crucible of cylindrical shape, is to be shipped separately. I want to say here that, in my opinion, graphite crucibles in any but the smaller sizes should always be packed individually. The practice, in which some manufacturers of crucibles still persist, of packing in hogsheads, not only gives the consignee an unwieldy package to handle, but often results in chipping and breakage.

The shape of the package necessarily must conform to the shape of the article or articles contained, as, for instance, shafting will require boxing the interior dimensions of which equal the exterior dimensions of the shaft. I think that shafting should always be boxed, after receiving a protective coat of paint, and if it is in sizes from two inches down, it is better to include several lengths in the same box rather than to make separate packages. Where conditions permit, the nearer a box comes to being a cube, the better, for several reasons.

SIZE OF PACKAGES. This should be governed more by the stated requirements for economical transport than by any other consideration, but, aside from these, uniformity and compactness are important. The ideal ship-

ment is one in which all the packages can be of the same size and form, as, for instance, borax glass or evaporated milk. Shipments of machinery or of mixed supplies cannot have this uniformity, however, and in such cases it must be left to the shipper to determine the best form and size. It is better to ship machinery 'knocked down' as much as possible, for safety as well as for convenience in handling.

WEIGHT. The foregoing paragraph applies here also, with the added remark that weight cuts a greater figure in the matter of convenient handling than does the size or form of a package. I should say that weights from 50 to 150 lb. are the most convenient for meeting general conditions, 100 lb. being the ideal weight because it is within the capacity of one man's handling. The cost of moving packages increases rapidly with any increase in the number of men required to perform the operation.

CHARACTER OF MATERIAL. Excelsior is no doubt the best material for filling, and the most generally used. If the article is fragile, it should first be wrapped in soft paper, and if a number of such articles of similar shape are nested, each must be wrapped separately, so as to prevent contact. If it is of such a nature that it may be injured by moisture, it must be wrapped with waterproof material, or, better, if of metal subject to corrosion, it should be given a coat of grease. When shipping delicate machinery or apparatus, it is a wise precaution to line the case with tar-paper, or other waterproofing.

Sawdust, straw, and paper are poor materials for filling. The first because it will run out if the package is broken, and if exposed to wet it becomes soaked, causing corrosion, due to the organic acids it contains. The second will become moldy and will cause heat and possible combustion if wet. The third is unsatisfactory because, if crumpled, paper does not hold the included articles in place; while if used flat it adds too much to the weight. This does not refer, of course, to the use of corrugated cardboard, which, when the conditions warrant the added expense, is one of the best of filling materials; it is particularly adapted to use in sending small packages by parcels post. This and similar materials may be regarded as special, however.

As to the choice of material for the construction of the container, there is frequently but little opportunity to choose, but when there is, the best is none too good. The best may not be the most expensive; for instance, in the choice of timber, from which most boxes are made, one that combines strength with lightness and freedom from splitting is the best. It is probable that spruce combines these qualities more than any other wood, with white pine as second choice and Oregon pine as a close third. Redwood, while light and free from the tendency to split, is not strong, and, besides, is usually too expensive.

I am not going into the matter of how to build a container, for the professional packers employed by our exporting firms know how to build and reinforce a box far better than I do, but I want to say that all packages for export should be well and tightly bound with strap-iron before shipment. Twisted wire binding is even bet-

ter, for it is not so apt to rust through, and is cheaper than strap-iron of equal strength. Some exporters make the mistake of using strap-iron that is too light, with the result that the case arrives with the binding either rusted through or broken in handling. Another advantage of wire over strap-iron for this purpose is that it is more difficult to tamper with a package. This is often an im-

AN EXAMPLE OF GOOD PACKING AND GOOD MARKING

portant consideration in places where light-fingered gentry abound.

QUANTITY OF PACKING MATERIAL. Use plenty, but not too much. Sage advice, you will say. How much is plenty depends entirely on what you are shipping. For instance, pipe, bar-iron, stamp-shoes and dies require little or none at all, while a surveying instrument or an analytical-balance will require a great deal. I will say, however, that in general when shipping heavy supplies or machinery to foreign countries, it is better to err on the side of too much than too little packing material. As a rule, the ends of packing-cases for heavy goods should be of two-inch, and the sides of one-inch, lumber. If the ends are of one-inch, they must be reinforced around the edges with one-inch material for proper nailing and for strength. When there is any doubt as to strength, it will pay to use two-inch material forthwith. Frequently it pays to salvage material at the point of delivery, where labor is cheap, and it is well known that more can be salvaged from two-inch than from one, so that the expense due to the added weight, size, and quantity of lumber may not be a dead loss.

DISPOSITION OF GOODS IN PACKAGES. I believe it axiomatic that no two decidedly different classes of goods should go into the same package if it can be avoided, especially if one is heavy and another light. If it be necessary to pack more than one piece or package of the same kind or similar in weight, they should have filling interposed, and if a heavy piece has to be included, it should be well secured from shifting. When several castings are placed in the same box or crate, as is sometimes advisable, each must be secured in place, to prevent shift-

ing and breakage. I consider it a mistake to put two pieces of finished machinery in one box, for the results are too serious in the event of one or the other breaking loose. Machinery, after stripping and packing separately down to the main frame, should always be bolted to strong stringers which later can be used as skids, the bolts, of course, going through the bed-plate holes, with the heads, supported by washers, in counter-sunk recesses below. The floor beneath the stringers is usually made heavier than the sides and forms the base on which sufficient boxing and crating is built, to protect the machine. This usually can be quite light, and should preferably have openings in the sides, to render it more likely that it will be kept "right side up with care". The superstructure must be built sufficiently strong, however, to stand having other heavy packages piled on it in the hold of a ship, for it is here, and in loading and unloading, that more breakages occur than at any other point. All rabbitted bearings must be specially protected from injury and all cut gears and other finished surfaces should be painted or greased.

Pulleys and gears are probably more subject to breakage on a journey than any other line of machinery. As these are expensive and so very important to operation, I wish to devote some space especially to the packing of these parts of machinery.

Each pulley or gear should be packed in a separate case or crate, unless there are a number of the same diameter,

A SHIPMENT OF LABORATORY APPARATUS FOR EXPORT
Photograph by courtesy of Braun-Knecht-Heimann-Co., San Francisco

when they can be packed together to advantage. Each case should be square, with internal dimensions equal to the outside diameter of the pulley or gear and the face thereof in thickness, to ensure a snug fit. If there are keys or set-screws, these should be wrapped securely, and wired to a spoke or to the hub. If the pulley or gear is fairly heavy, the enclosing square should be of two-inch lumber, and, if very heavy, the sides also. Ordinarily, however, the sides can be of one-inch stuff, with safety. The sides need not necessarily be closely boarded, but better protection is afforded at little additional cost by having them so. There should in no case be blocking or filling

of any kind within the case, as this may easily be the cause of breakage, in case weight comes on the side of the case, as frequently happens in the hold of a ship. Any such pressure transmitted to the hub or spokes is likely to cause damage, for the pulley or gear then becomes a beam supported at the ends and loaded in the middle. Pulleys and gears are not built to stand a transverse strain of this kind. This applies especially to a pulley or gear in which the length of the hub exceeds the width of the face, for then the side pressure comes directly on the hub. No harm ordinarily results from this, however, if the spokes and rim are left free, for the pulley or gear is free to move as a whole, and the sides of the box would have to be broken before damage could ensue. No piece of machinery should ever be shipped with the pulleys or gears in place, if it is practicable to remove them for separate packing.

MARKING. Each separate piece of goods for export should be marked plainly with the name and mark (if any) of the consignee, the name of the shipper, the destination of the shipment, the weight and dimensions of the package, and the net weight of the same, as well as the serial number corresponding to the shipping manifest. A copy of the packing-list should be included in each case, or attached to each bundle. The marks, preferably stencilled, should be made with paint that will withstand moisture and that will not rub off. The attaching of tags to bundles is a mistake. Iron or steel bars or pipe that do not require crating should be made up into bundles of convenient size, well secured by wire or iron clamps, and each bundle should be plainly marked with white paint. There are hundreds of plates or bars of steel or lengths of pipe kicking around customs-houses in various parts of the world because of failure to take these precautions.

I shall not attempt to go into the details of the checking of goods, for that is a story in itself, with which every exporter should be familiar. Suffice it to say that every lot of goods should be double-checked by responsible and capable persons, and that the greatest care must be taken in having the manifest agree with the checked list, to avoid subsequent trouble for all concerned.

In closing this article I shall recount an experience that illustrates how much trouble, expense, and delay can be caused by a shipper disregarding the instructions of a customer. In 1919 a 250-kw. generator, the arrival of which had been awaited anxiously for some time, was received at Manila by the company with which I was connected. Despite definite requests that this be shipped in two or more packages, it arrived in one, which was as large as a shack and weighed over five metric tons. It was considered risky to attempt to take it down and repack the rotor and stator separately, and it was necessary to get it to its final destination as quickly as possible on account of the approaching rainy season and because it was badly needed.

The transfer involved shipment by rail for 150 miles, haulage by wagon 35 miles from tidewater to an altitude of 5000 ft. above sea-level, unloading and transfer on

planks up-hill for two miles over a temporary road of about 8% grade, then sliding it down a steep ridge for another mile to the power-house. At the railroad the housing was all removed, leaving the skids and floor, and the generator was well wrapped with canvas and waterproof material, for the rains were already beginning. It was then loaded on an Army wagon, which fortunately was available, and the first lap of six miles or so was made by towing with a $1\frac{1}{2}$ -ton truck. This brought it to the foot of the grade, where a road-roller was attached and the rest of the journey was made in this way. Progress was slow but sure, and the trip was completed in ten days. It was then unloaded and transferred to the highest point above the power-house, this being accomplished by using snubbing-posts, block-and-tackle, and planks, the pulling being done with the truck mentioned, working down-hill on the fall-line of the tackle. Then came the real task, that of sliding a five-ton piece of machinery down a grade that in places was as steep as 45°. In two days more, however, it was safely landed at the bottom, with the aid of about 60 natives; and every one connected with the affair felt free once more to take a full breath. How much of trouble could have been saved us, had the shippers regarded our instructions. Remember, the man on the ground usually knows conditions and knows what he wants better than anyone else possibly can know. An observance of his requests is likely to lead to repeat orders.

A CONSERVATIVE estimate of the available potential water-power in the United States is 60,000,000 hp. Segregated according to States, we find that the State of Washington stands first with 9,500,000 hp. or 15% of the total potential water-power in the United States. California stands second with 9,250,000 hp. or 14.6% of the total, and Oregon ranks third with 7,000,000 hp. or 11% of the total. These three Pacific Coast States together represent 40.6% of the total potential horse-power of the United States. Including with these the States of Idaho and Montana, we find that the five Western States alone have a total of 35,750,000 hp. or 57.1% of the total potential water-power of the United States. Of this available power, only a comparatively small percentage of the total has thus far been developed. Of the 60,000,000 hp. of the United States only 15% has been developed. In California only 10.2% of the 9,250,000 available or 942,000 hp. is being utilized. In Washington the rate of developed to potential power is even less, being only 3.8%, while in Oregon it is only 3.5%. Comparing these with other sections having lesser amounts, we find that in the New England States 77.2% of the available water-power has been developed. It is a significant fact that while we have, west of the Rocky Mountains, only approximately 8% of the population of the United States, yet we have 68% of all of the available water-power. The Western States as a whole stand first in their per capita consumption of electricity, the use in this territory being 2.2 times as great as the usage in the remainder of the United States.

Organic Troubles

By Charles T. Hutchinson

Cadmus, the Phoenicians, or whoever it may have been that invented books, and, *ergo*, was responsible for the printed word as a means of transmitting and preserving thought, certainly started something. Had the starter realized that he or they would be held primarily responsible for what is known as the house-organ, they would have thought at least twice before inflicting this dire pestilence upon a world already fed up with a sufficiency of troubles.

Organs, of a kind, like the poor, are always with us, and always will be. With organs of the pipe variety, we have no immediate concern, nor shall we deal with reed organs. Rather it is organs intended to be read that we purpose presently to dissect, analyze, and otherwise reveal in their true colors. Organic troubles have fastened themselves upon the body economic. The world is simply plastered with organs, some of them monthly and many of them weakly if not actually poorly. Organs have become almost epidemic in business circles, greatly to the congestion of waste-baskets, ash-cans, and refuse-heaps.

When Moses slid down Mt. Sinai, and sold to the Israelites that famous group of slogans now nationally known as the Ten Commandments, he employed no advance agent, nor did he patronize billboards, subway-cards, or sandwich-men. The mouth-organ did the trick, his own mouth through which was emitted so effective a sales talk, that he put them over at a single sitting.

It was no cinch in those days. No man's voice had a national circulation, and there was no Associated Press whereby the dictum of Moses or any other alleged prophet could be transmitted rapidly to every household. Now that civilization, so-called, has achieved a lot of complexities equaled if not exceeded by its physical as well as mental growth, the human voice as an advertising medium is a back number without the assistance of the telegraph, the telephone, and the printed word. We poor humans, who love to talk about ourselves to the exclusion of all other subjects, were fast becoming limited to those of our friends whom we could button-hole in their unguarded moments, and even they were getting increasingly wary and difficult of access. So, what was to be done? Advertise ourselves we must, come what may, for otherwise who should know how great we are, we admit that we are, unless we could stress the first person singular, and show conclusively that the human biped is not merely two-eyed but Argus I'd.

Sound travels at the rate of 1090 feet per second, so the physicist tells us, but, when the space to be compassed is considered, the range of the *vox humana* is inconsiderable, and certainly falls far short of gratifying the insatiable thirst for the limelight that demands an audience without limit.

Little by little, during the countless ages, the ingenuity

of man evolved merrily through the transition from the hieroglyph and the parchment to the first printing-press with its crude hand-carved wooden type to the present day when the devilish ingenuity of Mergenthaler joins hands with the massive cylinder presses of Miehle; so that, in spite of Mr. Burleson with his hazards and bunkers in the form of zone postal-rates for second-class matter, it is possible for one man, or a group of men to exploit themselves to the suffering proletarians, in number limited only by the size of the purse of the propagandist.

That venerable document, the Declaration of Independence, guarantees to all of us the right to the pursuit of happiness. Therefore, when man has complied with the Freudian principle of satisfying his hunger, and acquiring a wife, the very next step in this never-ending pursuit is the exaltation of his ego.

Many and devious are the ways employed in this most absorbing of all occupations. The stage beauty, who immersed her pulchritudinous form within a bath-tub full of milk, and trusting in its protecting opacity, admitted a flock of newspaper reporters, differs merely in method from the public man who employs a press-agent to issue bulletins about him at regular intervals, or the manufacturer who causes to be printed an alleged 'journal' full of what is commonly known as 'bull', about himself and what he has for sale.

There are degrees in all things, and house-organs are no exception to this rule. Some of them are good, even excellent, and in point of real information compare favorably with the real honest-to-goodness publications that are sold on their merits and cannot be obtained in any other way. However, the pill is really there under the coating of sugar, however sweet or thick it may be, and the recipient knows it is a pill too, and in consequence is becoming more and more wary as he gains experience in the ways of the house-organist.

The time was, some years ago, when, in search of ways and means for exalting his ego, the egotist was content with the opportunities afforded by the public press as it then was, and, beyond the hiring of a press-agent to disseminate alleged 'news' items among the various publications, no individual effort was necessary. Now, alas, all is changed. Those good old times have gone, never to return. The editors, to say nothing of the business managers in charge of the affairs of the press, suddenly awoke to the fact that they were giving away a commodity that had a market-value. Worse than that, even where they were willing to sell space, they insisted that it be plainly labeled 'advertisement', which, of course, killed the effect that the self-seeker was after.

Thus, the editor has become a lynx-eyed cold-hearted person, with an uncanny faculty for smoking the Ethiopian from the press-agent's woodpile, however cunning-

ly he may be concealed therein. As the strings became tighter, there was developed a corresponding skill on the part of the seeker for publicity, and, occasionally a story gets by the editor that turns out to be nothing more than the usual wolf in sheep's clothing. These occurrences are rare, however. The bars are up, and permanently, and no charter member of the Capital I Society can rest content with the meagre opportunities afforded him by the press as a whole.

What was to be done? Answer: the house-organ, a personally conducted and personally controlled publication, whereby old man Capital I himself can root for himself until the cows come home, and without restriction in any way, other than the size of his purse.

Thus came into being the house-organ, and their number has waxed apace until now they are as many as the sands of the sea. Of course, they are distributed gratis, for who would buy them? No man is immune from their onslaught, for in this great and glorious free country of ours anyone can mail to anybody else as much trash as he pleases, provided that such matter be not libelous, and conforms to our liberal postal regulations. That the individual involuntary recipient of the house-organ has learned to detect such things almost instantly, and has acquired a remarkable degree of skill as a marksman through his ability to chuck them into the waste-basket from ten to twenty yards, is regarded as a thing of small consequence by the house-organist. There is a chance, always a chance, that the victim may at some time unwittingly be cozened into perusing its pages before he detects the hook on which the delectable worm has been impaled. The fact that the reaction from this discovery is not quite what the house-organist would desire is subordinated to the fever of the chase, with the huntsman never losing hope that ultimately he may close with his quarry and deposit it in his game-bag.

As the house-organ idea developed, the more intelligent organist began to acquire a certain fundamental knowledge of journalism, principally that in order to be effective the organ must be read, and that to be read it must be interesting. So many of the better house-organs are cultivating the reader's interest by using the soft pedal a little more when they pull out the self-interest stop, and otherwise seeking to cloak the journalistic freebooter so attractively as to disguise as much as possible its real purpose. This added to the expense of publication, so much so in fact that many of the better and too many of the worse house-organs began the solicitation of paid advertising by reason of the large distribution, not circulation, that they had to offer.

On any logical basis, this plan is difficult of execution. The buyer of advertising space has learned how to appraise its value by years of painstaking study and experience, and has developed certain criteria that have become axiomatic. The most important of these is that only paid circulation is of any consequence. Consequently, on its merits, the free distribution of the house-organ should automatically estop it from any considera-

tion whatever. But, alas, man works in devious ways his purpose to put over, so a new angle was devised to get advertising for the house-organ, and, unfortunately, it works to a certain extent.

Many big corporations, and other organizations about which more later, have become the champion house-organists. They, in turn, are not merely sellers, but buyers of quantities of raw materials and certain finished products. How simple it is for the advertising solicitor to obtain from the purchasing agent a list of all those from whom the house-organist buys, and, armed with this potent ammunition, seek them out one by one, gently conveying the impression that an advertisement in the company's house-organ would do no harm, while not supporting the enterprise of their valued customer might make a most disagreeable impression upon the purchasing agent when they, in turn, sought business patronage. A hold-up? of course it is, and almost at the point of a gun too, but nevertheless it is done every day, and unfortunately it is a growing evil that ought to be vigorously stamped out.

Whether those in authority knowingly connive at such methods may be questioned, but feebly. No alibi, however specious and plausible, can absolve the bosses themselves from what is done by their hired men. The victims in most part give up their money with a shrug of the shoulders, and say, with an air of resignation, "You see how it is. How can I help myself? I can't afford to jeopardize my standing with them. They are one of my best customers, and, if they take this method of getting part of my profit away from me, I have to add it to my overhead charges and let it go at that."

Associations, both trade and, alas, professional, have become eager seekers for a share of this easy money. Nowadays no co-operative association of similar business interests seems complete without its house-organ. It is not difficult to sell the house-organ idea to a co-operative association, with so many apparently prosperous similar enterprises springing up like weeds all around them. The eternal ego in all men is the real reason behind their easy compliance, backed by promises of distribution only limited by the size of the war-chest, and the absence of the restraints placed by legitimate publications that must and will protect their readers.

If the truth were known, much of this apparent prosperity is nothing but a sham. In the great majority of cases, the house-organ is far from self-supporting; in fact, most of them would succumb at once, if the subsidy from those most interested were to be withdrawn. They are little else but a bit of flotsam tossed about by the tide of business, pandering to the vanity of the house-organists themselves, the red-ink balance at the end of the year being accepted with the same philosophy as the large donation to charity, provided that a gratifying amount of personal publicity accompanies it.

Even the professional organizations seem to have succumbed to the temptation. Their case differs somewhat from those of avowedly commercial organizations whose obvious purpose is money-making, and, by the same

token, there is less excuse for them. Members of an engineering society pay dues for two reasons, one of which is for the prestige which membership gives them, and the other for the Transactions. The latter, if carefully selected and edited, constitute a valuable reference library in the practice of their profession. For these two considerations, they pay about \$15 per year, or three times the cost of a first-class technical periodical.

What inspired the professional societies to enter the house-organ field is a nice question; as a matter of fact, there are still one or two of them who are maintaining their obligation to their membership by sticking to their original purpose, variously expressed in their constitutions as the "advancement of science". With some of the others it has been the retreat of science, and the advancement of something else, whatever it may be. From the dignified, orderly Transactions, with their carefully selected professional papers, there has come a journal of sorts, filled with the gossip centring about headquarters activities, in which a ridiculously small proportion of the membership can participate, a number of accounts of the peregrinations of various officials, the trips they took, the banquets they attended, and the speeches they made, and other padding generally called 'Society News', and, perhaps, a perfunctory digest of technology from current periodicals and even an article or two of more or less interest. It is thin, even anæmic, and, this should be whispered, little other than a vehicle for such advertising as the proponents of the house-organ idea have succeeded in cajoling manufacturers into taking.

The line of attack in soliciting differs in some respects from that pursued by the other house-organs. There is first the plea of the high professional character of the membership, without, of course, explaining that the house-organ is forced down the throat of the membership, who put up with it for the sake of the Transactions that appear yearly. If that fails, there is the sympathy dodge, "Friend, feed me lest I starve" idea, where the advertising is solicited frankly as a donation to a worthy cause. Then, last but not least, there is the threat, real or implied, that the engineer is apt to be more friendly in his purchases to those who use the advertising section of the journal than to those who withhold their patronage.

Really, in the final analysis, it is all one and the same thing. In mathematics, the thing is to state correctly the hypothesis. In publishing or other aims in life, it remains to discover the motive. Since the imputation of motives is always a dangerous pastime, one may only theorize as to the real inward 'why' of it all. It would seem at least reasonable that the council, board of directors, or whatever they may be called, of the engineering society lately turned publisher, succumbed to the plea of possible profitable business with more money available for the expansion of the society's activities. The proponents of the idea, the paid secretarial staff of the society, saw, in the embarkation into a business enterprise, increased emoluments for themselves without the attendant risk associated with a business that must stand or fall upon its own merits.

The great lack in all such publications is the one thing without which outside advertising cannot be conscientiously solicited, and that is, reader interest. Reader interest can easily be claimed, and, of course, always is, by any advertising solicitor. Claims are one thing, however, and proof is another, and reader interest can be proved conclusively upon no other basis than the actual payment in cash by the subscriber for the publication. Free distribution is of little or no value to the advertiser; distribution of a publication to members of a society or association free, or in part consideration for dues or assessments, is little, if any, better; the only circulation that is, on the face of it, clearly and definitely valuable to an advertiser is that which is bought and paid for in cash by readers because they want it.

All of these things are clearly understood by the better advertising agencies, and by the Audit Bureau of Circulations, whose reports differentiate clearly between the many classes of publications upon this general basis. They are also understood by advertising managers for business enterprises, so, when considered upon their intrinsic value as advertising media for anyone other than the publisher, they would receive scant consideration. Therefore, the form of solicitation is generally that already referred to, and offers considerations that are little more than a jimmy with which to pry orders from the helpless buyer of space.

Again, publishing is a business, requiring skill, training, and experience. The pitfalls are many, and a group of doctors, dentists, engineers, or what-not, who blandly jump right into the middle of things and think because perhaps they have become passable doctors, dentists, or engineers, they would make regular prima-donna publishers, are apt to experience a jolt that will paralyze the pocket-nerve, or worse, the pocket-nerves of the individual members of the society or organization into whose treasury they have so gaily dipped in the quest of easy profits. There is one case of this kind already that will require a lot of explaining, as to the why's and wherefore's of more than double the annual dues in order to make up the deficit of the past year's experience in the publishing business.

Man, collectively and singly, is queer fish at best. It has been said that the only real difference between man and the lower animals is that between reason and instinct. Sometimes, however, one is inclined to be somewhat in doubt about the evidence of reason as exemplified by some of the things we do. We follow fads and fancies, just as surely as the sheep follow their leader, blindly, instinctively. House-organs have become epidemic, so instinctively.

House-organs have become epidemic, so what ho! let us have a house-organ. Everybody's doing it, and then everybody overdid it, and now, in the general process of deflation, the house-organ too, when subjected to the scrutiny of the microscope, stands before the real economist, naked if unashamed. The ash-cans are full of them, and, in fulfilling this function, the ash-can is one of the noblest works of man.

Consumption of Reagents Used in Flotation

By Thomas Varley

***INTRODUCTION.** In April 1919, as a result of many requests received from individuals and mining companies for such information, the U. S. Bureau of Mines sent to milling and ore-dressing plants a questionnaire asking for data on the tonnages treated both by gravity concentration and flotation, the tonnages of concentrate produced by each system of milling, and the consumption of oil, acid, and other reagents, as well as the kinds used, these returns to cover the calendar year 1919.

It was hoped to issue a report by mid-summer of 1920, but much delay was experienced in collecting the data. Some of the companies refused to give such information, although most of them made prompt and complete returns. However, replies have now been obtained from practically all plants, and the following statement has been prepared. The figures presented are representative and complete enough for all practical purposes.

The reports showed that there was 26,545,564 tons of ore of all kinds treated by flotation, from which 3,105,343 tons of concentrate was produced, showing a concentration ratio of 8.55:1.

The total amount of oil, acid, and other reagents used was 113,510,234 lb., equivalent to 4.2384 lb. per ton of ore treated. Of the total quantity of ore treated, by far the greater part was copper ore. Tabulations for the various ores are given in detail, showing a summation of all reports received.

GOLD-SILVER ORE. Not many reports were received from companies treating ores of gold and silver. In the plants making reply, there was treated 75,081 tons of ore, yielding 8698 tons of concentrate, a concentration of 8.63:1. Oils used were petroleum fuel-oil, 42,054 lb., pine-tar oil, 24,720 lb., and turpentine, 36,320 pounds.

GRAPHITE ORE. The number of tons of graphite ore treated was 55,980, yielding 906 tons of concentrate, a concentration of 6.18:1. Oils and reagents used were pine-oils, soda ash, and lime, aggregating 250,700 lb. in all.

MISCELLANEOUS ORES. This class includes ores of the rarer metals, such as molybdenum and antimony, and complex mixed ores of various kinds. There was treated 73,690 tons, yielding 5840 tons of concentrate, the ratio of concentration being 16.62:1. Oils and reagents used were sodium sulphide, 73,360 lb.; soda ash, 133,770 lb.; sodium silicate, 111,136 lb.; and pine-oils, 22,786 pounds.

COPPER ORES. In tabulating the returns for copper ores, all plants that were treating ore solely by gravitation methods have been excluded. Many companies, however, use a combination of gravity concentration and

flotation. Usually flotation supplements gravity concentration, although in a few plants the reverse was reported.

Of 38,255,707 tons of ore milled, 23,265,832 tons, or 60.8%, was treated by flotation. This would indicate that 39.2% was discarded as tailing low enough in metal content not to warrant re-grinding for further treatment, although a certain small proportion would represent concentrate removed by concentration machinery.

The total amount of oil, acid, alkaline reagents, and all other flotative reagents used averaged 4.6360 lb. per ton of copper ore treated. In the following table the total amount of each reagent used is also calculated as the average number of pounds consumed per ton of ore. This figure, of course, does not represent the average consumption in any one flotation plant, but nevertheless is of interest. Some plants use large quantities of one reagent, either oil, acid, or alkali, whereas another plant may not use any of the flotative reagents employed at the former plants.

It will also be noticed that the oils have been grouped somewhat under general headings. All the special brands of coal-tar have been grouped, also various brands of coal-tar creosote, hardwood creosote, pine-oil, pine-tar, etc.

The total amount of copper ore treated by flotation was 23,265,832 tons, producing 2,837,660 tons of concentrate, a concentration ratio of 8.23:1. The following table shows the kinds and amounts of oils and reagents used for this tonnage.

Reagent	Pounds	Equivalent in pounds per ton of ore treated
Coal-tars	20,488,275	0.8787
Coal-tar creosotes	1,399,170	0.0601
Hardwood creosotes	1,774,722	0.0767
Pine-oils	2,142,065	0.0920
Pine-tars	1,064,199	0.0498
Fuel-oil	212,985	0.0099
Sulphuric acid	70,290,505	3.0254
Caustic (kind not stated)....	1,570,200	0.0675
Kerosene acid sludge.....	7,935,200	0.3402
X-cake	228,740	0.0099
Xilidine	188,472	0.0088
Turpentine	23,310	0.0009
Other oils	375,000	0.0161

Total average number of pounds of oils and other reagents used per ton of ore treated... 4.6360

LEAD AND LEAD-SILVER ORES. The tonnage of lead and lead-silver ores treated by flotation is considerably less than that of copper ores. This may be due to the fact that in the former, the valuable minerals are more concentrated than in copper ores, in which the mineral constituents are generally finely disseminated.

Flotation generally supplements gravity concentration,

*Published by courtesy of the U. S. Bureau of Mines. The author is metallurgist in charge of the Salt Lake City station.

and a large tonnage of material or tailing low in metal content can be discarded. This is especially true in the south-eastern Missouri lead district.

The returns show that the total quantity of these types of ores treated by combined gravity and flotation methods was 6,742,815 tons. Only 1,671,740 tons, or 24.78% of the total tonnage reported, was treated by flotation. This 1,671,740 tons re-treated by flotation produced 147,552 tons of concentrates, a concentration ratio of 11.33:1.

A list showing the oils and other reagents used for treating this tonnage, and the amounts consumed, follows:

Reagent	Pounds	Equivalent in pounds per ton of ore treated
Coal-tars	324,861	0.1943
Coal-tar creosotes	71,860	9.0430
Hardwood creosotes	642,051	0.3840
Pine-oils	221,416	0.1324
Pine-tars	22,904	0.0135
Wood-tars	86,926	0.0520
Crude petroleum	318,544	0.1905
Sodium sulphide	151,212	0.0904
Cresylic acid	12,069	0.0072
Sulphuric acid	98,027	0.0586
Kerosene	9,707	0.0057
Gasoline	2,934	0.0017
Soda ash	95,210	0.0570
Sodium silicate	144,371	0.0863
Nitre-cake	161,270	0.0964
Other reagents	86,720	0.0517

Total average quantity of oils and reagents used per ton of ore treated by flotation.....1.4647

ZINC ORES. The reports show that 2,917,443 tons of zinc ore was treated by combined gravity concentration and flotation, 1,563,482 tons or 53.59% of the total tonnage being treated by flotation alone. This yielded 211,302 tons of concentrate, a concentration ratio of 7.39:1. The oils and reagents and the amounts of each used for this tonnage follows:

Reagent	Pounds	Equivalent in pounds per ton of ore treated
Coal-tar creosotes	21,110	0.0013
Hardwood creosotes	31,742	0.0020
Copper sulphate	81,145	0.0518
Pine-oils	1,741,674	1.1136
Crude oils	11,238	0.0007
Other oils and reagents.....	63,300	0.0041

Average quantity of oils and reagents used per ton of ore treated2.5578

GENERAL REMARKS. The most generally used flotation reagents for copper ores are sulphuric acid, kerosene acid sludge, and the coal-tars. For lead and lead-silver ores, hardwood creosote is used the most, followed by coal-tars, crude petroleum, and pine-oils in the order named.

Most important for zinc ores are the pine-oils, which constitute 43.5% of the total quantity of oils used for this ore, with copper sulphate and hardwood creosote next in importance.

Among the other reagents used are such materials as

sulphur; specially prepared and fractionated oils, of coal-creosote, wood-creosote, and pine-oils; also various sodium salts, ammonia, and ammonium salts.

Low-Grade and Complex Ores in Colorado

It has been recognized that the metal-mining industry in Colorado has been on the wane for several years, mining now ranking fourth among the basic industries of the State. This marked decline of metal mining from its former supremacy is due partly to the unusually rapid growth of the other industries and partly to the decrease in mineral production both in quantity and value. With a view to aiding and encouraging metal mining a fund of \$15,000 was made available by the State for an investigation of the low-grade and complex ores of the State, to be undertaken jointly by the U. S. Bureau of Mines and the Colorado School of Mines. The object was to determine the character and approximate extent of these ores, and where found in sufficient quantity, to conduct concentration tests at the Golden laboratories in an effort to devise a cheap and suitable treatment.

The metallurgical work was under the direction of W. H. Coghill, metallurgist, assisted by C. O. Anderson, J. P. Bonardi, and Max Shapiro, of the Bureau of Mines, and J. C. Williams and E. V. Engels representing the State. The first step was to make a careful physical examination of the ore, followed by chemical analysis to determine the content and character of the minerals present. If this showed that the valuable minerals present were so intimately associated or 'locked' in the ore that they could not be readily separated, then methods of treatment were applied which experience had shown would be most likely to give the desired results. Twenty-nine of the ores submitted were examined and their amenability to concentration determined insofar as time permitted. The principal processes tried were flotation, gravity concentration, and cyanidation. The most promising results were obtained by using flotation combined with gravity concentration. Differential flotation, or flotation of one mineral in advance of another, to make a complete separation, is not applicable, except in rare instances, to Colorado complex ores. From the complex sulphide ores galena and the precious metals were recovered as far as possible by gravity concentration. To recover the finest grains of galena, the chalcopyrite and the remainder of the gold and silver, means had to be devised to float them in advance of the sphalerite. Sodium sulphide was found to be a valuable reagent in this step. Results in the laboratory tests with sodium sulphide, and with an acid solution of sodium dichromate to grade up the zinc by flotation, have been so successful that they should receive further attention. The principal function of the dichromate was to remove the iron sulphide from the zinc, but it also removed some of the lead, silver, and gold. The oxidized ores were tested principally by cyanidation, but some flotation tests were made. Some of the ores were readily amenable to cyanidation; but others proved refractory.

Karl Eilers v. Guggenheims

233 Broadway, New York City, January 31, 1921.

To the Stockholders of American Smelting & Refining Company.

Sirs:

Probably you have wondered at and perhaps been concerned about the situation in your Company.

Its stocks have declined far below those of other supposedly good industrials.

Its net earnings have declined so as to be changed into losses.

Its cash has declined so that the Company has become a large borrower.

Its directing head has declined and tapered down from a Daniel Guggenheim to a Simon Guggenheim.

Its organization has declined in morale, efficiency and personnel.

Its dividends have declined and its chances of increased dividends are steadily declining.

Its business prospects are declining, particularly since the recent gift of the copper sales agency (heretofore worth more than a million a year) to Guggenheim Brothers.

Why? Why?

Your Company should be managed by and for its owners—you stockholders—and not for any outside interest.

The Guggenheim family formerly owned a very large stock interest—probably the actual control. They absolutely dominated the Company.

When either because of or in spite of this domination the Company had grown and a broad market had been established for its stock, the Guggenheims quietly sold out "on the other stockholders" to the extent of practically all their stock. It then being to their interest, perhaps they really did do a good deal toward placing the Company in such good position—that they could profitably sell out. At any rate, up until after that time Mr. Daniel Guggenheim gave to the matter his personal attention.

Since then, taking their profits and investing them elsewhere, the Guggenheims have had larger financial interests in other concerns with interests conflicting more or less with those of your Company. However, they have held on to the control of your Company largely because of the prestige and strength it gave them in handling their own enterprises. They still absolutely dominate your Company because you stockholders have not awakened to the alarming situation which has been greatly intensified by these changes. That the Guggenheims themselves are quite awake to the change occasioned by their disposal of their stock interest is shown, perhaps, by the fact that, except in matters affecting Guggenheim interests, Mr. Daniel Guggenheim has ceased to bother with the affairs of your Company, and whatever vision and

direction it gets has to come from his younger brother, Simon.

They gave an illustration of their absolute domination and of their disregard of stockholders at the last election. They used the proxies, confidently sent them by the stockholders, to drop me from the Board (and they now speak of me as a discharged employee) although the Company's books show that I was by far the largest stockholder on the Board. I happened to be personally in a financial position which allowed me to question Simon Guggenheim's plans and policies when they were not in the interest of the stockholders, and often I had found it necessary to do so. The sole ground of my removal—obligingly given in advance in writing by President Simon—was that I was not in accord with him.

The Guggenheim management of Smelters has but just now transferred as a *gift* from your Company to Guggenheim Brothers contracts for copper sales agency or brokerage which brought the Company in net proceeds of over \$10,000,000 in eight years. No characterization of this amazing transaction is necessary. The Guggenheims, apparently, thought they had to say something and have sought to do two difficult, if not impossible, bits of explaining—that is, to justify this *gift* and to excuse certain past losses incurred in gambling in copper—by playing one questionable act off against another in making the absurd claim that the gambling was a necessary part of the brokerage.

Do you, an owner of Smelters, believe that the Guggenheims, who are but slightly interested in Smelters and very largely interested in Guggenheim Brothers, should have had the "say" as to handing over that valuable business? Should they have the say as to the making of smelting contracts with mining companies in which they are interested more largely than in Smelters?

Although in the *fourteen* years, ending June 30, 1920, the capitalization and debt of the company have been largely increased, no possible benefit therefrom has accrued to the stockholders. The net quick assets per \$100 of capitalization and debt show no increase. And on the contrary the dividends on the common stock have declined from $7\frac{1}{2}\%$ to 4% per annum.

The Guggenheims have resented criticism by the real owners and have run your Company, with which they are little concerned, as a convenient side enterprise of their own.

For instance, they have turned over to Smelters for approximately \$22,000,000 in cash and its equivalent some of their poorer mines. But by a remarkable series of coincidences neither Chile, nor Braden, nor Utah nor Nevada Con., nor any other of the wonderful successes offered to the Guggenheims ever found its way into Smelters or was offered to its stockholders, but went where the Guggenheims personally were more interested.

That is, Smelters paid them for less successful mines, but never even by accident did it get any of the remarkably good opportunities which came to the Guggenheims originally because of their positions in Smelters.

The domination of the Guggenheims is to be regretted not only for many things which they have done, but also for many things which they have not done, and even more for many things which, by merely occupying the positions of power and initiative, they have kept others from doing. Perhaps the greatest of all the evils due to their domination is that it has prevented, and, if continued, will prevent your Company from having a management of its own of responsibility and initiative.

To remedy this is of the utmost importance, and can be done, I believe, with very few changes in the management if the Directors are made to owe their position to the vote of the stockholders and not to the whims of the Guggenheim family. The removal of the Guggenheim threat with the opportunity of freedom of action to the Directors and management will immediately increase the opportunities, efficiency and energy of the Board and the organization, and will benefit the Company almost at once and automatically.

Very large salaries (amounts kept secret even from the Directors but believed to aggregate more than \$500,000 each) have been paid by your Company to a number of members of the Guggenheim family who were more interested in other concerns and who devoted most of their time and real effort to other matters. To what end were they given these offices and salaries? Since they sold out, certainly not because of their investment in the Company. Were their services of such value? The *Mining and Scientific Press* of San Francisco seems to hint to the contrary when it says: "To put it bluntly, would Mr. Simon Guggenheim be engaged as the Chief of the enterprise on account of his knowledge of mining and metallurgy, or of the business relating thereto, on his own merits as a technician and financier?" . . . "Similarly, most of the brothers and nephews might not be picked by other people to manage a mining and smelting business of large dimensions."

It has been the policy of Smelters and of other large industrial corporations to require their higher salaried men to make contracts to devote their "entire time, energy and skill" to the service of the Company. Were the numerous Guggenheims required to make such contracts?

If not, why not?

If so, what rights has your Company in the enormously valuable Chile Copper and other properties to the organization and development of which they devoted so much of the "time, energy and skill" which must have belonged to your Company?

The sum total of such salaries paid to the members of the Guggenheim family is very large, but it is as nothing compared with the value of opportunities which the Guggenheims sent elsewhere or compared to other possible losses due to having the actual management of the Company in the hands of those who were not primarily con-

cerned with the Company's financial success but were personally interested in the success of other and sometimes conflicting concerns, even if they had no intent to divert profits from your Company.

The vital necessity to this Company is an administration actively, solely, energetically and devotedly attempting to give it the best possible management and to bring to it all possible opportunities.

The lack of public confidence in the management has been indicated by the low average price and wide fluctuations of even the preferred stock of the Company, notwithstanding its excellent dividend record.

Do you wish your Company absolutely controlled by a group which has sold out practically all its stock, and at the same time has retained or acquired large holdings of other companies with conflicting interests?

Do you wish your Company to be controlled by those who give to Guggenheim Brothers, in which they are more largely interested, business which had been worth more than one and a quarter million a year?

Do you wish your Company controlled by men to whose personal profit it is to give the good opportunities to other companies in which they are much more largely interested and who have sold their poorer mines to your Company and turned their rich opportunities to other companies?

Do you wish your Company controlled by men who are much more largely interested in other enterprises with which Smelters will have business dealings than they are in your Company itself?

Do you wish the Guggenheims to determine what gifts shall be made—what contracts handed over—by Smelters to Guggenheim Brothers?

Do you wish your Company which naturally should be one of the greatest and most profitable industrials in the world and could easily be made so with an absolutely independent control and with competent management, to have a management whose financial interests would not actually be in the Company's success?

A number of stockholders, holding and representing substantial amounts of stock which have been practically in the same ownership since the formation of the Company, are co-operating to help the stockholders. Neither I, nor any other of these stockholders, is seeking any office or any personal gain other than through the enhanced value of his stockholdings. Our efforts are directed entirely to the correction of conditions for the benefit of all the stockholders.

A preliminary letter sent out on January 6th has resulted in the receipt of a large number of proxies and of many letters necessitating individual reply, which will be answered personally. It is desired to obtain the co-operation and assistance of as many stockholders as possible; in fact, the co-operation and assistance of the great body of stockholders will be absolutely necessary if they are to obtain the control of the Company for themselves and in their own interests. It will be required to overcome the proportion of proxies always automatically and thoughtlessly sent in to the management of a large

company, regardless of the achievements or errors of that management, and also to overcome the assistance which may be rendered the Guggenheims by their powerful associates in other enterprises.

This letter will be sent to all known stockholders, including those who have already replied to the former letter.

Please sign and return the enclosed form of proxy.

If those stockholders who feel disposed to assist by some personal activity in the effort to help themselves and all the stockholders, will so advise, some of us here who are interested will be pleased to correspond with them as to joint efforts to be made in their respective localities.

Very truly yours,

KARL EILERS.

The Economic Situation in Mexico

When the general depression that affected Europe began to spread to Latin America last summer and exchange sharply declined, attention was turned to Mexico, with hope for continued active markets, states a consular report. Mexican currency is today worth more on United States markets than that of any other country in the world, and the exchange rate has been recently above par. But in the latter part of November and in December occasional reports came in of the closing of mines and smelters; the price of silver began to drop at an alarming rate; the cotton crop was less than normal, and part of it was sold at prices below cost of production. Bank rates were raised, money became tight, and finally the Banking Company of Paris & Mexico went into the hands of receivers, and the Mercantile Banking Corporation was obliged to close its doors. The ports were badly congested, the railways were hampered by lack of equipment, both suffering from the results of labor troubles. Unemployment began to appear and wages were lowered, but the cost of living, particularly with regard to rents, continued to increase. It was reported that a large number of silver, copper, lead, and iron mines had been compelled to close, throwing about 10,000 miners out of work.

In spite of these unfavorable features, however, there is much in the situation to inspire confidence. The attitude of the Government has been in favor of the establishment of sound conditions. A new banking law is promised, which is calculated to encourage investment in Mexico. The President published a decree on January 11, 1921, providing that when the market value of electrolytic copper in New York City drops to 15c. or less per pound, the export duty is to be removed. A report from Commercial Attaché Jackson on January 19, 1921, states that the Banking Company of Paris and Mexico, under a receivership, and the Mercantile Banking Corporation were expecting to re-open within a few days. Another indication of expected prosperity is the opening in Mexico City of a branch of the American Banking Corporation on January 19. The production of coal is being

resumed and the railways are provided with fuel now that the Sabinas coal strike is settled. The oilfields are prosperous in spite of congestion at the seaports, for the production of petroleum is greatly exceeding all previous records.

An Ingenious Filter

By A. T. FRY

The accompanying sketch shows a vacuum-filtering funnel which may be of interest. It is usually an advantage to see the filtrate when using vacuum, though by the use of a large opaque receiver, there is little risk of losing any solution. The usual vacuum flasks with side tube have lately been of indifferent quality, so I devised this funnel to make common glass acid-bottles available for use. The size of the neck of these bottles

is not large enough to permit using a two-bore cork, so I brought the vacuum tube in through the side of the funnel, down the inside of the stem and out about an inch above the stem end where the filtrate flows. Thus there is little risk of filtrate being sucked into the vacuum pipe.

A short piece of rubber tube slipped over the stem makes a good joint in the neck. The funnel may be made of iron for work with cyanide solutions, though copper or lead may be more suitable in other cases. The perforated plate should be stiff enough to remain flat when the suction is applied, for convenience in fitting papers in subsequent operation.

It is an advantage to solder a disc of 60-mesh screen on top of the perforated plate, blanking its edge with solder, thereby covering the edge of the paper in the usual way.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

GOOD ORE DEVELOPED IN DEAN MINE AT KINGMAN.

KINGMAN.—Financing of the National Five Gold Mines Co., that has taken over the property adjoining the Arizona Mossback Mines Co. to the south, has been completed. Charles H. Burlock, who was owner of the Arizona Mossback properties prior to their being acquired by the Arizona Mossback Mines Co., has been negotiating the deal with Arizona and Eastern capitalists. The property of the National Five Gold Mines Co. is on the same vein as the Arizona Mossback and near the old workings on the vein from which rich ore was taken in the past. The present plans of operation include the installation of equipment to sink to the 500-ft. level. Quarters for men and a pipe-line to Cottonwood creek, where water will be obtained, are to be constructed.

The Dean mine, which is situated 15 miles east of Kingman in the Maynard district, is carrying on development with about 30 men. A large body of ore 80 ft. to the east of the main cross-cut and averaging 14 oz. silver per ton for 14 ft. has been opened. In the west drift 90 ft. from the old raise a streak of ore 30 in. wide assays 300 oz. silver per ton. In the intermediate drift to the east of the old stope the vein is 12 ft. wide and is said to average 60 oz. silver, part of which occurs as native silver.

OATMAN.—A hoist moved from the Hi Henry mine has been installed at the Baltic mine, which lies to the north of the United Western and to the west of the Gold Road mine. Sinking is to be commenced immediately.

The drift on the 650-ft. level of the Gold Ore has reached the orebody, the width of which is to be determined immediately by cross-cutting. It is said that the ore at present exposed is high-grade mill-ore, but a better grade is expected, as this ore at the surface averaged about \$100 per ton.

TOMBSTONE.—A strike of high-grade silver ore, the largest that has been made in the district in recent years, has been made on the old Dragon claims by lessees. The vein opened is said to be eight feet wide and will assay \$89 per ton.

COLORADO

GOOD OUTPUT FROM CRIPPLE CREEK MINES.

BLACK HAWK.—Sinking has been resumed from the 200-ft. level of the Silver Mountain Mining Co.'s main

shaft. Ore shipped from the bottom level has averaged \$160 per ton. The ore averages $\frac{3}{4}$ oz. gold and 15% lead, the remainder of the value being in silver. The shaft will be sunk an additional 60 to 75 ft. before running a new level, on the theory that the top of the shoot has been cut. The company has recently taken over the Linden Castle under bond and lease and is cross-cutting from the Silver Mountain tunnel to intersect the Linden Castle vein at depth.

CRIPPLE CREEK.—The January output, as compiled by

PART OF SOUTH-WESTERN ARIZONA

mill and smelter reports totaled \$425,111. The 35,556 tons of ore shipped averaged \$11.95 per ton. The treatment follows: Golden Cycle mill, 15,000 tons of an average value of \$15, gross value \$225,000; Portland G. M. Co.'s Independence mill, 17,556 tons of an average value of \$5.56 per ton, bullion value \$97,611; Lincoln Mines & Reduction Co., 1000 tons averaging \$2.50 per ton, \$2500; smelters, 2000 tons averaging \$50 per ton, \$100,000.

Ore running from 6 to 29 oz. in the main Portland

vein at the 2450-ft. level is being developed with the drift. At the 23rd level the shoot was nearly 900 ft. in length and the grade high. Production has temporarily stopped from the No. 2 shaft to permit of the installation of the hoist formerly in use at the Gold Coin shaft of the Granite Gold Mining Co. in the city of Victor. The Granite company operations are now conducted from the Dillon shaft.

SILVERTON.—The Henrietta Silver Mines Co. is extending its tunnel, now in 400 ft., to cut the main Henrietta vein, that, in the shaft workings, averaged around \$35 per ton. The management has announced that its stock is not on the New York curb, but stock of another Henrietta company with properties in Colorado is listed. Negotiations are reported in progress looking to a merger of the two companies.

TELLURIDE.—Concentrate shipments from mills in the district in January amounted to 98 cars. The production at the several mills follows: Tomboy, 42 cars; Smuggler Union, 41; and Liberty Bell, 15. Construction of the flotation unit of the Smuggler Union plant has been delayed by heavy snowfalls. The walls nearing completion will now be covered with temporary sheet-iron roofing while machinery is being installed. Tetrahedrite ore assaying better than 100 oz. silver with some gold has been opened in the No. 2 tunnel of the Butterfly property at Ophir Loop by the Matterhorn Mining & Milling Co. Smelter shipments are reported as returning about \$125 per ton. The vein was cut at a point 700 ft. from the surface in undeveloped territory. Stoping is under way with the shoot holding its width and richness.

LEADVILLE.—Lessees on the Fanny Rawlins mine are producing and shipping about one car per week of rich sulphide ore, mined between the third and fourth levels, while lessees working on the first level have opened up strong bodies of lead ore, and operators on the second level are mining a good grade of gold-copper sulphide ore. The Fanny Rawlins company paid a dividend last year from royalties received.

MICHIGAN

HUGE CAKES OF COPPER EXPORTED TO GERMANY.

HOUGHTON.—The Michigan Smelting Co., which smelts mineral from the Copper Range mines—Champion, Baltic, and Trimountain—loaded 560,000 lb. of copper this week for Germany. This is the first copper sold by this smelter to Germany for a year and a half and is considered a hopeful augury. A shipment of 500,000 lb. went out this week from the same smelter to the Detroit Copper & Brass Rolling mills. This cleans up all big orders to date. The shipment for Germany was in the form of cakes weighing 6800 lb. each. The cakes were among the largest ever poured at the smelter, the size being according to specifications in the order. It is not known to what use they will be put. It required the erection of a derrick to load them on the cars. The shipment to Detroit was in the usual commercial sizes. Quincy is mak-

ing no shipments for export, but is shipping some metal East, as is Calumet & Hecla.

The Calumet & Hecla electrolytic plant at Lake Linden has been closed temporarily. It has been operating at only 50% capacity since the shut-down of Calumet & Hecla subsidiaries on November 16. Most of the silver recovered in the electrolytic plant came from the Osceola lode of Calumet & Hecla, Osceola Consolidated, including Kearsarge, Isle Royale, and White Pine. Of these, Isle Royale is the only one now operating and the plant will not re-open until a sufficient amount of Isle Royale silver 'rock' is accumulated.

Copper Range is taking on more men at its Champion, Baltic, and Trimountain mines, particularly at Champion. Champion has been down to as low as one-quarter its maximum underground force. Normally this mine employs 1200 men in actual mining operations. While it is not the intention to bring underground forces up to normal, in view of the continued depression in the metal market, a much better organization will be built up so that the shafts will be in position to take immediate advantage of any marked advance in the market. Baltic and Trimountain have from 40 to 50% of their maximum 1915-'16 force. Many of the men now being employed come from the Gogebic, Marquette, and Menominee iron ranges and are former residents of this district.

NEVADA

TONOPAH DISTRICT IS THRIVING.

TONOPAH.—Bullion shipments for the last half of January show that the rate of production at the Tonopah mills is the greatest in the history of the district. The production of the Tonopah Mining, West End, Mac-Namara, Tonopah Extension, and Belmont for the last half of January was 224,853 oz. of bullion, valued at \$277,800, or at a rate of more than \$6,650,000 yearly. The output of the mills includes bullion from ore shipped from nearby districts, but this is regarded as a minor factor.

WEST DIVIDE.—A second cross-cut on the tunnel, or 150-ft., level of the West Divide has entered the vein 150 ft. from the first cross-cut and a drift has been started from each cross-cut to connect them. A drift from the first cross-cut has for 40 ft. been in ore 2 to 4 ft. wide that assays \$100 to \$250, according to official statements, and the second cross-cut is in \$80 to \$100 ore. After the drifts have connected the cross-cuts an inclined winze is to be sunk in the vein and if the ore is persistent it is reported that shipping will be started and continued while a new shaft is being sunk to replace the present one, which cuts the vein at a depth of 50 ft. Ore of widely varying width and grade, but with an indicated average width of 3 to 4 ft. and an average value of \$70 to \$100, has been opened at depths of 50, 70, and 150 ft., the last representing about 200 ft. on the dip of the vein. Most of the work has been done at 50 ft., where the north drift is in a continuous ore-shoot for 70 ft., the lowest assay being 62 oz. silver and the highest 300 oz.

Rich ore was found south of the shaft at this depth, but the shoot is not persistent in this direction.

KLONDYKE.—It is reported that an engineer representing Eastern interests has completed an examination of the Original Klondyke, now being worked by lessees, and that there is a good chance for the mine to pass into the hands of men who will develop it thoroughly. The Knox is shipping at a rate of 25 tons daily, the ore assaying \$25 to \$30 in carload lots, and this rate of shipment is to be increased. The Lucky Boy Divide is moving machinery from Divide to claims owned by the company adjoining the Knox and it is reported that mining is to be started in 60 days. The Ben Hur is starting work far north-east of the Knox, and the Portland Klondyke is operating for the first time in many years, money

pushed from both ends. The total footage of this work during January was 364. Work is also progressing satisfactorily on a connection between the 1800-ft. level of the Chief and the Eagle & Blue Bell properties, which will improve ventilation in both mines.

Development work is being carried on at the May Day property through the Yankee Consolidated shaft. This work is on the 1800-ft. level and is almost directly below some of the older workings of the mine on the 1100-ft. level, where ore was found. It is stated that a raise will be put up from the 1800-ft. level.

During the week ending February 4, the Tintic Standard shipped 67 cars of ore; Chief Consolidated, 37; Iron King, 15; Eagle & Blue Bell, 13; Iron Blossom, 12; Victoria, 7; Dragon, 7; Gemini, 4; Centennial-Eureka, 4;

A LARGE BLAST AT THE MOTHER LODE MINE, GREENWOOD, B. C.

having been raised by J. B. Witt, formerly connected with the Witt-Brandon lease on the Florence Goldfield, through the sale of stock in Tonopah and Goldfield. It is reported that the Gold Seam is to ship.

UTAH

SILVER KING COALITION COMPANY PLANS TO RE-BUILD MILL AT ONCE.

EUREKA.—On February 2, the Chief Consolidated Mining Co. paid a dividend of 5c. per share, or a total of \$44,211. During 1920 the company paid quarterly dividends of 10c. per share, but the slump in prices of metals, together with extraordinary expenses in connection with sinking and concreting No. 2 shaft, rendered it advisable to cut the dividend. By February 20, a second connection will be made between the old workings and the new shaft at a depth of 1800 ft. At present there is a connection on the 1000-ft. level. In order to hasten the work on the 1800-ft. level, headings are being

Grand Central, 2; Gold Chain, 2; Bullion Beck, 1; Colorado, 1, making a total of 172 cars.

PARK CITY.—Conditions are reported as excellent at the Park-Utah mine by Paul Hunt, superintendent. This property is making steady shipments and has a total of 40 men on the payroll. A compressor and new mine-cars have been ordered to facilitate development work. The Park-Utah is controlled by the Judge interests.

Shipments from the Silver King Coalition have dropped off considerably as a result of the fire on January 27. During the week ending February 4, the Judge allied companies shipped 785 tons; Silver King Coalition, 273; and the Ontario, 205. The Judge smelter shipped 35 tons of premium spelter.

At a meeting of the directors of the Silver King Coalition Mines Co., on February 8, it was decided to begin immediately the work of preparing plans for a new concentrating plant. Construction will begin as soon as the weather permits, according to W. Mont Ferry, managing director. Inasmuch as the foundations of the old struc-

ture were unharmed by the fire, the new mill will be built on the same site. Several plans regarding the handling of mill-ore, while the new plant is being constructed, are under consideration. At the time of the fire, G. W. Lambourne, president of the Judge M. & S. Co., tendered the Coalition company the use of any mill equipment the Judge company owned. The portal of the Alliance tunnel is close to one of the Judge mills, and concentrating ore could easily be transported through the tunnel to the milling plant.

BRITISH COLUMBIA

GRANBY CONSOLIDATED WINS SUIT.

VANCOUVER.—On February 3, the Granby Consolidated Mining, Smelting & Power Co. virtually won its two appeals against the decision of Justice Gregory, which gave the Esquimaux & Nanaimo railway title to the Cassidy collieries, now being operated by the Granby company. The Granby company was given full title to Dunlop property, and the Court found that title to the Ganner property was vested in the Granby company, but in case of assessment for damages in respect to the coal rights these are to be considered as 'coal in nature'. The outside price at this rate is stated to be \$150 per acre, so for the 200 acres involved the utmost that the Granby company would have to settle would be \$30,000. The counsel for the E. & N. Ry. gave notice of appeal to the Privy Council. The Granby company has spent fully \$2,000,000 on the development and equipment of these coal areas.

PRINCE RUPERT.—The output of the Granby company for December was 2,665,018 lb. of copper. The Drum Lummon mine, at Hartley Bay, is to be re-opened on April 1 under the management of C. A. Collins, and a hydro-electric plant is to be installed to replace the present internal-combustion engine plant. The mine yields both gold and copper ores, which in the past have been concentrated together; it is proposed to treat them separately in the future. The net earnings of the Belmont-Surf Inlet Mines, Ltd., for the quarter ended September 30 amounted to \$68,640.

POUNCE COUPE.—The Imperial Oil Co. has shipped an extra heavy oil-rig to Stiff River, whence it is to be hauled over the snow, and drilling operations are to be started here as soon as the weather permits. The site chosen for the boring is said to be just on the Alberta side of the inter-provincial boundary-line.

STEWART.—The Nabob group, in the Portland Canal district, is showing up well. Considerable tunneling has been done and latest reports state that 12 ft. of solid ore has been disclosed, both the hanging and foot-walls being well defined; the former is a black slate and the latter a well mineralized porphyry.

ONTARIO

INCREASED TAX ON NET PROFITS OF MINES IS BEING OPPOSED.

PORCUPINE.—The Supreme Court of Ontario has decided a long-contested dispute between the Township of

Tisdale and the leading mining companies, as to whether their mills were liable to municipal taxation, in favor of the companies. 'Concentrators' are exempt from local taxes under the Assessment Act, but the township contended that the term 'concentrators' only applied to mills using mechanical processes, and that the use of cyanide being a chemical process took them out of the exempted class. The decision of the court relieves the Dome, McIntyre, Davidson, and several other companies from local taxes on properties valued at about \$2,000,000.

The result of work on the 850-ft. and 1050-ft. levels of the Dome Mines has shown greatly increased enrichment of the ore at depth. A large tonnage of ore occurring in wide veins at the 1050-ft. level yields over \$20 per ton, as compared with about \$6 carried by the ore hitherto treated.

The Premier Paymaster, in the vicinity of the Dome, on which some \$100,000 was spent before it was compelled to close down, will shortly be re-opened, having been successfully financed in Boston. The shaft will be put down to 100 ft. to develop an orebody indicated by diamond-drilling.

COBALT.—Reports now in preparation by the mining companies in the district will show a general decline in ore-reserves as of the end of the year 1920. This decline is due in part to the shortage of labor which existed during the first nine months of the year, as well as to the power shortage during the closing quarter. It is chiefly due, however, to the decline in quotations for silver. This has relegated a large tonnage of silver-bearing material to the classification of waste. The McKinlay-Darragh is expected to show a decline of close to 50%, with a decline of upward of 25% for the Nipissing.

A financial statement issued by the Nipissing shows liquid assets of \$4,921,010 as of January 3. This was prior to the distribution of a regular 5% dividend plus a bonus of 5%, which called for the payment of \$600,000. A feature in connection with the Nipissing is that the dividends were distributed among 13,000 shareholders, making an average of about 92 shares held by each stockholder.

During 1920 the Crown Reserve Mining Co. experienced an operating loss of \$72,054. The surplus was reduced to \$512,481, which is equal to about 25¢ on each issued share. The company received no dividends during the year from the Porcupine Crown mine, which it controls.

The Ontario Minister of Mines has issued an advance notice that the mining-profit tax of the Province may be increased this year. The present tax is 3% on the first million dollars earned, and 5% on all amounts exceeding one million. The proposed increase would impose 4% on the first million with 7% on all amounts exceeding that figure. This increase would apply to the silver and gold mines, and a general protest has been raised in the silver and gold mining districts, where the belief exists that the Government should reduce the difficulties under which the industry labors rather than create an additional burden.

THE MINING SUMMARY

PROPOSED INVESTIGATION OF A. I. M. & M. E. AFFAIRS

Following the receipt of the notice of a \$10 assessment to meet an impending deficit in the finances of the Institute, the San Francisco Section addressed the following resolution to the directors in New York on January 11, 1921.

"The San Francisco Section is not entirely in accord with the action of the finance committee of the Institute in debiting the members' accounts with a charge of \$10, leaving the payment or non-payment of same to the discretion of each member, with no alternative to pay a lesser amount.

"The Section desires to be advised regarding the necessity for this action, which appears to be establishing a dangerous precedent.

"With no desire to criticize the action of the committee in adopting such course, the Section respectfully suggests that a committee be appointed to examine (and report on) the finances of the Institute and to submit a report with recommendations; whereby the future expenses of the Institute shall not exceed its income.

"The Section suggests that the committee shall consist of seven (7) members, three of whom shall be thoroughly conversant with editorial and publication work."

This elicited a reply addressed to C. H. Fry, secretary of the San Francisco Section and signed by Bradley Stoughton, secretary of the Institute, quoting from the minutes of the directors' meeting and urging prompt action by the San Francisco Section. The quotation from the minutes reads:

"Appreciating the deep concern in the welfare of the Institute which has been characteristic of the San Francisco Section, and sensible of the continued support which the Institute can always expect from our Pacific Coast members, the board of directors would ask the San Francisco Section to suggest the personnel of the committee which it has spoken of in its recent communication, in order that the investigation proposed may be conducted in a manner and by persons entirely acceptable to our San Francisco members.

"Resolved, that the officers of the Institute be instructed to furnish the San Francisco Section full information to carry out the proposed investigation."

At the meeting of the San Francisco Section held on February 8 it was decided to suggest the following representative members of the Institute, who reside in or near New York, to serve on the investigating committee: C. R. Corning, Arthur S. Dwight, Walter R. Ingalls, E. W. Parker, and Robert M. Raymond.

FINANCING THE SURPLUS COPPER

Plans for financing the sale for export purposes of 400,000,000 of the 600,000,000 lb. of surplus copper in the American market have been made public, with the announcement that the product was pledged as security for \$40,000,000 8% notes of the Copper Export Association, to be offered for public sale by a banking syndicate headed by the National City Co. and the Guaranty Trust Co. of New York. The inclusion of companies outside the Copper Export Association is an important feature, as it is certain to result in more rational viewing of the copper problem by all concerned. As a result the loan becomes one of far-

reaching importance, and should prove in its indirect results to be one of the most constructive moves that have been made to help tide the copper industry through this period of depression. This is said to be the first large public loan made in this country to be secured specifically by a certain amount of an essential commodity, as well as the first big movement by American companies to take advantage of the opportunities offered under the Webb export trade act to invite public participation in the financing of foreign trade. Under provisions of the Edge law, allowing combinations for export trade only, agreements as to price and supply may be entered into, and on this account the copper to be pooled must be 'ear-marked' for foreign consumption.

The heavy accumulation of surplus copper was the result of the sudden ending of the War and the inability of European consumers to take their usual requirements. The 400,000,000 lb. is only about three-fourths of the export trade done by this country last year and, in the opinion of producers, if marketed over a reasonable period it will be easily absorbed. The present rate of production is said to be below the deliveries of copper in 1919 and 1920, making a further heavy accumulation improbable. The notes to be issued for the loan are being offered at prices to yield from 8 to 8.30%. The current price of about 13c. per pound compares with an average market price for refined copper of 16½c. over the last 20 years, and with a low record price during that period of 11 cents.

THE MAYO DISTRICT IN THE YUKON TERRITORY

Reports from Dawson indicate that the Mayo district in the region of the Upper Stewart river has been developed to a point where its permanence as a productive mining locality is assured. Geologists and mining engineers who have visited Mayo state that a zone having every formation favorable to extensive silver-lead deposits runs athwart the area for at least 25 miles, with a width of 10 miles. Within this strip there are eight hills upon which locations have been made and development done with excellent results. Nearly a thousand claims have been staked in these localities, which are known as: Keno Hill, Lookout Mountain, Stand-To Mountain, Rambler Hill, Galena Hill, Galena Creek, Mount Hinton, and Mount Cameron. Veins from several inches to five feet wide are said to have been discovered and the assays reported range from \$200 to \$5000 per ton in silver and lead. Returns from \$200 to \$500 are common. The Yukon Gold Co., which is proceeding with extensive development, plans to have 3000 tons of sacked ore hauled out this winter for shipment by water by way of St. Michael when navigation opens.

ALASKA

Juneau.—D. C. Jackling, of the Alaska Gold Mines Co., has announced that a portion of the milling and power plants, owned by the company and originally constructed to treat the gold ores from the Juneau mine, will be converted into wood-pulp mills. The raw material is obtainable in the vicinity of the company's property, and in view of the fact that the mining operations have been conducted at a loss for some years, the change seems logical.

CALIFORNIA

Amador County.—The work of repairing the caved workings on the 3900-ft. level of the Argonaut mine is practically completed, and unwatering below that level will be resumed. The objective is the 4900-ft. level, where high-grade ore had been exposed prior to the time when the mine was flooded to overcome the fire. Among the mines employing many miners are the Central-Eureka, Old Eureka, Fremont, and Bunker Hill. All of the towns in the vicinity show signs of returned prosperity such as prevailed prior to the War.—The Morning Star company is preparing to increase the capacity of its mill at Mokelumne hill from 250 to 1000 tons per day. It is reported that the main orebody is 75 ft. wide and that recent developments have largely increased the ore-reserves. The company is also sinking a shaft at the Moser property.

Nevada County.—H. L. Ostrander, manager of the Alta-Combination placer mine, has completed the erection of a saw-mill, air-compressor, shops, and power plant, and is ready to proceed with underground work. The adit is expected to tap the old Alta Hill channel, which yielded good gravel years ago.

San Francisco.—At the regular monthly meeting of the San Francisco Section of the A. I. M. & M. E., held on February 8, C. M. Eye gave an excellent paper on 'Development of the Mineral Resources of the Philippines', and E. H. Clausen spoke interestingly on 'Geology and Mining Conditions in the Aroroy District'.

San Pedro.—Excellent results are being obtained from tests made by Fred Thomas at Harbor City, for the purpose of perfecting a scheme for manufacturing zinc oxide. An antimony plant, built during the War at a cost of \$200,000, has been acquired. The zinc oxide is not of as good grade as it is hoped to make, but further improvements in the manipulation are expected to result in a better product. M. P. Kirk, at one time manager of the Yellow Pine mine near Good Springs, Nevada, is working on the process.

Ubehebe.—Four trucks are now hauling ore from the Arrowhead Rico, two having been added recently. Returns from the second carload shipment give a content of 59% lead and 35 oz. silver per ton. The lower tunnel will be completed in ten days. This tunnel was advanced 32 ft. in the last three days. It is being driven in soft lime and the contractor receives \$6.50 per foot.

COLORADO

Boulder.—The Tungsten Products Co. has made its first shipment of radium from the local plant. The product, which is in the form of bromide, was worth \$50,000. It will be shipped to the company's laboratories in the East for further refining.

Dumont.—Work on the Bohanza group of mines on Mill creek is progressing. A tunnel 700 ft. long is being driven to connect with the shaft.

Georgetown.—The Denbigh Silver-Lead Mines Co. is extending the 13th level of the Terrible mine into new territory and is taking out ore necessary to this development. The vein contains a 12-in. seam of ore sampling around 100 oz. silver and \$10 gold per ton.

Idaho Springs.—The Gem Mining Co. is reported to have taken up the option on the Argo tunnel and mill, the purchase price being in the neighborhood of \$250,000. The Argo tunnel will be remembered as the old Newhouse tunnel, started in 1893. It is now four miles long. About 80 men are engaged in development work, including the lessees.

—The installation of a new 75-hp. hoist at the Freighter's Friend has been completed.—The Metropolitan mine, situated up Spring gulch and at the foot of Freeland gulch, will begin work soon. M. J. Reiley has secured a lease on both the tunnel and shaft.

IDAHO

Coeur d'Alene.—In the upper workings of the Success mine a vein of clean silver-lead ore averaging from one to three feet in width has been revealed. When the lessees started work they began drifting on a narrow stringer of ore, and it widened out in a short distance to its present width. The ore in the Granite contains silver and lead with little zinc except in the lower levels where the zinc content is important.—Operation of the West Sunset property, adjoining the Tamarack holdings, has recently been started from the shaft of the Sunset mine, which is 1000 ft. deep. The shaft was unwatered recently. It is reported that a 10-in. streak of high-grade silver-lead ore has been exposed.—Development work at the Silver Cable property in the East Coeur d'Alene district is soon to be resumed. The Silver Cable mine is situated seven miles east of Mullan, and is developed by two tunnels.—Leasing operations on the Dobson & Jim property, situated in Dobson gulch between Wallace and Murray, will be started soon. A shoot of high-grade ore a foot wide has been opened in the property and work will begin shortly, hand-sorting the ore and shipping it to the Bunker Hill smelter.—The Ten to One Mining Co. has been organized to take over and operate the property of the old Coeur d'Alene Silver-Lead Development Co., consisting of 18 claims in the Murray district, according to W. W. Johnston, of Spokane.

Lemhi County.—The total value, after paying smelter charges, of the output of the Pittsburgh-Idaho mine at Gilmore has been \$5,350,000. The principal metal is lead with considerable silver and a little gold. The company is preparing to sink its three-compartment shaft from the 700 to the 800-ft. level.

Montpelier.—The Pegram Mining & Milling Co., owner of a large deposit of low-grade gold ore assaying from \$4 to \$6.50 per ton, is preparing for the erection of a cyanide plant at its property near here. A carload lot of ore was shipped to Denver, where tests were made to devise the best method of treatment. The Oregon Short Line R. R. Co. has surveyed a spur track to the property.

MONTANA

Butte.—Two bills introduced in the legislature at Helena are meeting opposition. One imposes a tax on the net revenue amounting to one-half of 1%; 'net revenue' is considered to mean the remainder of the income after deducting payment for labor, supplies, and safety-first work, but exclusive of depreciation, betterments, additions, replacements, and salaries of officials. A second bill contemplates an increase in the rate of compensation for injured workmen. It is contended that such a measure is unwise, in view of the present unsatisfactory condition of the metal market.—The East Butte company has taken advantage of curtailed production to put the Pittsmtont mine in shape for maximum output at economical cost. Ore mined during the past six months has averaged between 4½ and 5% copper. The company has started shipping its blister copper to the refinery of the Anaconda company at Raritan, New Jersey, instead of to the Nichols plant on Long Island.—The Davis-Daly Copper Co. has reduced its operations to one shift, 225 men being employed as compared with 350 a fortnight ago; 200 tons of ore per day will be mined.

Dillon.—Henry Auerbach, president of the Silver Spring Mining Co., has taken four samples from an 80-ft. shaft on the company's property 21 miles south-east from here. The average assay is 20% copper, \$3.75 gold, and 2 oz. of silver. There are six veins outcropping on the surface. A 25-hp. gasoline hoist will be sent to the property.

Helena.—R. P. McDonald, interested in the Lee mine in the Rimini district, states that the company expects to erect

a mill to treat low-grade silver-lead ores being mined.—The State Railroad Commission has authorized the railway companies in Montana to reduce freight-rates on iron ore used for fluxing purposes at the East Helena smelter, from \$4.40 to \$3.30 per ton. The ore comes from White Sulphur Springs and is of exceptionally good quality for use in the smelter.—The adit of the Chicago-Montana property is being advanced, and within a month the vein of copper ore is expected to be cut. The same company owns the Economy mill near-by, which represents an investment of more than \$300,000.

NEVADA

Cuprite.—Ernest D. Foster states that the Foster Mines Co. had ordered machinery for mining and milling a large deposit of silica, which is to be shipped East to be used in the manufacture of glass. 'Pre-shrunk' silica, made by melting the crude product and re-grinding, is used for the manufacture of an especially good silica brick.

Goldville.—The recently planned remodeling of the mill of the Lynn Big Six Mining Co., 21 miles north-west of

Light M. & M. Co. will soon start operating under the supervision of W. W. Wells.

Tonopah.—The drift on the 1400-ft. level of the Tonopah Belmont, the lowest depth at which mining is being done, has exposed a full face of ore on the Belmont vein. This adds materially to the ore-reserves in the mine. The mill is working at capacity on ore from the Belmont mine and from other properties in Tonopah and Divide that send their ore on a custom basis.

UTAH

Beaver County.—The Gold Crown Mining Co. has shipped silver ore which averaged \$100 per ton, according to James Kirk, superintendent.—It is reported that the Beaver Copper Co. will resume operations about March 1. This property is 11 miles north-west of Milford, and has been developed by an inclined shaft to the 470-ft. level. Two cars shipped by lessees from this property recently averaged 40% lead and 17 oz. silver.

Bingham.—During 1920, the Utah-Apex Mining Co. produced 117,784 tons of ore, which yielded 1912 oz. of gold,

INTEROCEAN MINE, BOULDER COUNTY, COLORADO

Carlin, is progressing. The equipment consists of a gyratory crusher, compact screens, Hardinge ball-mill, amalgamating-plates, and Wilfley tables. R. M. Holt is secretary-treasurer for the company.

Mina.—The proposal of the Nevada-California Power Co. to remove its transmission line between Aurora and Hawthorne is being protested by the citizens of Hawthorne. The purpose of the proposed plan is to obtain material for the power-line connecting Millers with the Simon silver-lead mine.

Ploche.—L. G. Gillett, superintendent of the Virginia-Louise mine, has blocked out a large quantity of additional ore on the third and fourth levels of the mine. Development work on the fifth level is revealing a satisfactory increase in the ore-reserves.

Searchlight.—The Big Casino Leasing Co., of which M. D. Rossiter is superintendent, has repaired its main shaft to the 300-ft. level, preparatory to extracting ore from that level. The shaft will be cleaned as far as the 6th level.—The Duplex mine is shipping steadily to Salt Lake smelters. George R. Colton is managing director.—The Goodhope, adjoining the Quartette mine, is being rehabilitated by F. W. Knable and associates of Denver, Colorado.—The Search-

336,587 oz. of silver, 20,667,181 lb. of lead, 7,257,765 lb. of zinc, and 840,213 lb. of copper, the gross value of which was \$1,634,516. The company estimates the value of its property, for taxation purposes, at \$137,500.

BRITISH COLUMBIA

Quesnel.—The California-Cariboo Gold Dredging Co. has been incorporated under the laws of California, for the purpose of dredging the lower 10 miles of the Cottonwood river. The company intends to install a California-type gold dredge upon the completion of the Pacific Great Eastern railway to the Cottonwood about July. The officers are: E. L. Pilling, president; J. E. Platt, treasurer; B. H. Paul, secretary; and W. W. Wishon, engineer.

MEXICO

Monterrey.—Although reports have been received here of the resumption of mining and milling operations in the States of Durango, Chihuahua, and other parts of the country, the conditions in the Monterrey district are not so good. The American Smelting & Refining Co. shut-down its smelter here a few days ago and development work upon a number of the larger producing mines from which the smelter derives its chief supply of ore has been suspended.

It is stated that the smelter will probably not resume operations for several months. Several thousand employees were thrown out of work by the closing of the plant. Labor conditions in this part of Mexico are unsettled and this fact, together with the unsatisfactory metal market, is given as the cause for the closing down of the smelter and mines. The situation as regards fuel, which for a time threatened seriously to hamper the smelting and mining industry, is much improved. Enormous quantities of coal are being shipped into Mexico from the mines in Texas, especially those at Eagle Pass.

Tampico.—Exports of oil from Mexico for 1920 totaled 153,795,000 bbl., as against a total of 79,927,000 in 1919, an increase of 73,868,000 bbl., or almost 100%. The big companies increased their shipments from 3,000,000 to 16,000,000 bbl. each. Mexican Petroleum Co., the largest shipper for the year, exported 28,687,000 bbl., and showed a gain of 16,701,000 bbl. over 1919. Standard Oil Co. of New Jersey shipped 20,197,000 bbl. in 1920, an increase of 11,504,000. Mexican Eagle Oil exported 20,289,000 bbl., a gain of 7,765,000. Large increases in 1920 shipments were made by Island Oil, Texas company, Gulf Oil, and Sinclair Oil, ranging from 3,000,000 to 6,000,000 bbl. each.

Torreon.—Luis C. Ratto, representing the Santa Cecilia Mining Co., has taken up a number of new mining claims in the Ramirez mountains, near San Juan de Guadalupe. This company is composed principally of Americans who will develop several groups of mines in that vicinity. Their new properties adjoin the San Acasio group.—Jose Alonso, of San Antonio, Texas, was here recently on his way to the Tamazula mining district, where he has filed on some new claims which he is developing. The properties include two filings of several claims, each of which is traversed by veins of gold and silver bearing ores. Thomas Gaya has located a group of six promising prospects in the Panuco de Coronado region. The properties are contiguous to the Trinidad and Washington mines which have produced considerable rich ores. Mr. Gaya expects to be able to commence the shipment of ore during the coming month.

ONTARIO

Cobalt.—The Porcupine Associated Gold Mines, Ltd., has been organized with a capital of \$5,000,000. The purpose is to merge the interests of the La Palm, Three Nations, Dominion-Porcupine, and Veteran properties, the total area being 720 acres. Development work will be commenced at once.—Operators of silver mines are opposing the contemplated plan of the Government to increase the profit-tax on the mines of the Province. They point to the higher price being paid for silver in the United States as compared with that obtained for Canadian silver, as an argument against the proposed tax.

PERU

L. T. Haggin, of the Cerro de Pasco company, has estimated that last year's profits were at least \$4,000,000. This would be equivalent to approximately \$4.47 per share on 898,119 shares outstanding. The company appears to have been one of the few big copper producers that succeeded in earning its dividend last year. This estimate of 1920 earnings does not include undistributed profits of subsidiary companies which have amounted to something like \$1,000,000 annually the last four years. Cerro de Pasco is also affiliated with American Metal Co. in which it has an ownership of about 4500 shares, representing an investment of \$747,000. American Metal refines and sells its product. The company's copper production last year totaled 52,878,000 lb., against 58,124,000 in 1919, 71,906,800 in 1918, and 72,674,032 in 1917, its banner year. Today its silver output constitutes more than 11% of its annual metal production, and is increasing.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Robert A. Kinzie has returned to San Francisco from the west coast of Mexico.

Frederic R. Weekes has left New York for the West on professional business.

D. D. Moffat is visiting the Mesabi Iron Co.'s properties at Babbitt, Minnesota.

Ray J. Barber is now at Burlingame. He will open an office in San Francisco.

H. Vincent Wallace is leaving Los Angeles for Salina Cruz, Mexico, on February 21.

M. W. von Bernewitz has severed his connection with the 'Mines Handbook' at Tuckahoe, New York.

Eugene G. Snedaker passed through San Francisco on his return from Bagdad, Arizona, to New York.

L. S. Cates, general manager for the Ray Consolidated Copper Co., has returned to Salt Lake City.

R. B. Kepner has opened an office as consulting mining engineer in the Washington building, Los Angeles.

John M. Fox, superintendent for the Belmont Wagner Mining Co., has resigned and is now in San Francisco.

W. W. Wishon recently completed an examination of the Sixty Three group, on Stockton hill, near Kingman, Arizona.

G. W. Heintz, vice-president and general manager for the U. S. Smelting, Refining & Mining Co., was at Salt Lake City last week.

R. C. Gemmell has returned to Salt Lake City after visiting the Chino Copper and Ray Consolidated properties in New Mexico and Arizona.

Alex Schloesser has resigned as engineer in charge of the engineering department of the southern division of Miller & Lux, to accept a position with the Mexican Candelaria Co., at Durango, Mexico.

A. R. Elliott, formerly assistant petroleum engineer of the U. S. Bureau of Mines, with headquarters at the San Francisco office of the Bureau, has resigned to accept a position with the Pierce Oil Corporation at Oklahoma City.

E. L. Pilling, president, and **W. W. Wishon**, engineer, California-Cariboo Gold Dredging Co., recently visited San Francisco in regard to the purchase of machinery for the first dredge on the Cottonwood river near Quesnel, B. C.

J. A. Bancroft, professor of geology in McGill University, has been appointed assistant general manager for the Granby Consolidated Mining, Smelting & Power Co. He will take up his new duties at the close of the present university session.

E. E. Campbell has resigned the position of assistant general manager for the Granby Consolidated Mining, Smelting & Power Co., Ltd., at Anyox, B. C., to accept the position of general superintendent for the United Verde Extension Mining Co., at Jerome, Arizona.

Obituary

Abe Erickson, an employee of the Woodlawn Copper Co., at Alta, Utah, was electrocuted on February 4. A fire was discovered in the company's compressor plant, caused by a short-circuited wire. Erickson threw a bucket of water on the sputtering wire and fell dead. Officials of the company believe the electrocution was caused by the forming of a contact with a high-voltage power-line when Erickson threw the water on the short-circuited wire.

THE METAL MARKET

METAL PRICES

San Francisco, February 15

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	13.50-14.00
Lead, pig, cents per pound.....	5-8
Platinum, pure, per ounce.....	\$70
Platinum, 10% iridium, per ounce.....	\$100

Spelter, cents per pound.....	8.25
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

February 14.—Copper is quiet and firm. Lead is inactive but easy. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

SILVER'S DEFLATION

Like the other of the non-ferrous metals, silver shows little inclination to advance in price. The metal is now selling at under 60c. per ounce, or virtually the low of last December and compared with the high of \$1.37 per ounce in 1920, it has been more than cut in half. The market for so-called domestic silver still remains at 90½c. to \$1 per ounce, sustained by periodical purchases of silver from American mines by the Government to replenish the treasury. This silver must be bought at \$1 per ounce and only from domestic producers.

The meteoric history of silver during the war years is no less sensational than that of the rest of the metals. Stimulated by a world shortage, which was induced by a fear of paper money and consequent hoarding of the white metal by Europeans, the price of silver kept steadily rising. America was compelled to settle much of her purchases in Japan, the Orient, and India with silver dollars. Paper money in those countries is looked upon with suspicion and this country melted down and shipped over 240,000,000 silver dollars to Japan, India, China, and other countries of the Orient. The price advanced to \$1.37 per ounce.

The old economic truth that rising prices stimulate production again proved true. Silver was dumped on the market by European nations who found a profit in melting their coins and selling the bar silver in the open market. The crisis in Japan and to some extent in India cut off further demand from these sources and the metal had a precipitate drop from the high of \$1.37 to a low of under 60c. touched last December.

As a protection for American producers, the Treasury Department announced that under the Pittman Act the Government would begin purchasing back the silver it had melted at a price of not less than \$1 per ounce. This has stabilized the price for domestic silver.

Commercial silver is selling at about 60c. and the big producers of Canada and Mexico—Nipissing and the Cobalt operators above our northern border, and Greens-Canaana and Cerro de Pasco in the Latin countries—are prohibited from receiving the Government price of \$1 per ounce, being foreigners.

Up to the present time the Treasury Department has purchased back nearly 33,000,000 oz. of silver. There remain 178,000,000 oz. yet to be purchased. All this metal will be bought from domestic mines which on the rate of last year's output of approximately 54,000,000 oz., means the entire production of this country for the next four years, provided, of course, the treasury takes the metal as fast as produced.

The following table shows production of the United States and average prices for silver in the last 10 years.

	U.S. production, oz.	Average price, cents
1920	54,250,000	100.86
1919	55,285,000	111.50
1918	67,810,000	96.75
1917	71,740,000	81.41
1916	74,414,000	65.66
1915	74,961,000	49.69
1914	72,455,000	54.81
1913	66,801,000	59.80
1912	63,766,000	60.83
1911	60,399,000	53.30

MONEY AND EXCHANGE

Foreign quotations on February 15 are as follows:

Sterling, dollars:	Cable	3.92½
	Demand	3.93½
France, cents:	Cable	7.47
	Demand	7.49
Lire, cents:	Demand	3.76
Marks, cents:	Demand	1.75

Eastern Metal Market

New York, February 9.

Improvement in demand is only slight in some metals but prices are fairly steady to firm.

The copper market is firmer and demand is a little better.

A fair business has been done in tin almost daily with prices easy to steady.

Lead is very quiet and a little lower.

The zinc market continues lifeless with the quotations practically unchanged.

Antimony is nominally the same as a week ago.

IRON AND STEEL

Announcement by the Midvale Steel & Ordnance Co. that it would quote prices low enough to bring business to its mills, some of which have been shut-down since early December, has brought the steel market this week to a new stage in price readjustment. Thus far no large business has been done, but already cuts of \$5 per ton below the Steel Corporation's schedules are reported. There are plentiful indications that other independent steel companies stand ready to take a share of the going business, even though realizing that under present conditions there will be no free buying.

The crux of the new situation is the extent to which the wage reductions already made by some independent producers will allow them to go below Steel Corporation prices. These reductions have been from 15 to 25%.

Competition in steel from the continent of Europe looms up as a large possibility in all export calculations, Germany's chances growing better. Some German punching and shearing machinery undersold American machines in northern Ohio this week.

COPPER

The chief interest of the week has been the attempt to arrange a method of financing the 400,000,000 to 500,000,000 lb. of copper stocks. It is understood that this has been accomplished but the details are not yet available. The plan is to finance this metal for the export trade and the whole scheme is regarded favorably in all circles. Whether all companies will enter the arrangement is also not known. The effect of these plans on general sentiment has been good, so much so that the London market has advanced £2 to £3 per ton in the last week or about \$10 per ton in American money. Prices here are also slightly higher and the market tone is stronger. Electrolytic copper is quoted at 13 to 13.25c., delivered, for early delivery with 13.25 to 13.50c. asked for March-April. Lake copper is held at 13.50c., delivered. Demand, particularly from foreign buyers, is reported as improved.

TIN

The market has been fairly active at least up to Friday of last week, sales each day being estimated at 125 to 150 tons. Dealers were again the principal buyers, though consumers were also well represented. A quiet but steady business was done but the advance which started in London late during the week checked this movement. The market therefore has been very quiet since Friday. It has been many weeks since any sales have been recorded on the New York Metal Exchange, but on last Friday 75 tons was sold, all February-March-April shipment, at 32 to 32.50c. No definite news is yet available regarding the reported lowering of the Malay government's purchasing price to £205, but this is expected any day. Spot Straits, New York, has hovered around 32 to 33c., New York, the past week and was quoted yesterday at 32.50c. Prices in London were lower yesterday than a week ago at £164 for spot standard, £169 for future standard, and

£184 for spot Straits. Arrivals thus far this month have been 960 tons with 2535 tons reported afloat.

LEAD

Demand is light and the market is quiet and without feature. More consumers are covered by contracts on which deliveries are progressing regularly. Prices are a little lower than a week ago. The leading interest's quotation is unchanged at 4.75c., New York and St. Louis, but some independents are down to this level at New York and appear to be offering enough to satisfy present demand. The nominal quotation for spot is 5c., New York, with the St. Louis quotation at a minimum of 4.50c.

ZINC

Since last week definite information has been secured to the effect that 10,000 tons of German-made zinc was recently sold for shipment to this country. The sale was made at 4.50c. per pound in bond, which figures at about 5.12½ to 5.17c., duty paid. It is known that offerings of foreign zinc, probably German, have been made at around 5.25 to 5.35c., seaboard. While considerable has been made of this competition, it is not believed by some that the quantity available from that source is heavy. The market is stagnant and "sick", to quote one seller. Demand is very light and shows no improvement. Prime Western is quoted at 5c., St. Louis, or 5.50c., New York, for the domestic metal, and for the foreign product, when available.

ANTIMONY

There is little activity and quotations are nominally unchanged at 5.25c. per pound, New York, duty paid for wholesale lots for early delivery. Jobbing lots are about ¼c. per pound higher.

ALUMINUM

There has been a misunderstanding abroad regarding the quotation of the leading interest which is 28.20c. f.o.b. producer's plant, for virgin metal, 98 to 99% pure, in wholesale lots for early delivery. From other sellers who handle foreign aluminum the quotation is 24 to 25c. per pound, New York. The market is a little more active.

ORES

Tungsten: No improvement is reported and the market continues dead. Chinese ore is held at \$3 per unit for February-March shipment.

Molybdenum: Inactivity still characterizes the market with quotations nominal at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: No business is reported and no inquiry. Importations were again heavy in December at 59,248 gross tons, bringing the total for 1920 up to 601,437 tons, or close to the war record of 1917. Quotations are nominal at 35 to 40c. per unit, seaboard.

Manganese-Iron Alloys: Spiegeleisen is more active with about 250 tons sold and inquiries for 150 tons before the market. Prices are \$40 to \$45, furnace, but this has been shaded by some of the business done. There is no demand for ferro-manganese which is quoted on a basis of \$100, seaboard, but which could probably be obtained as low as \$100, delivered. Imports in December were 5424 tons, bringing the 1920 total to 59,204 tons, or the heaviest in several years. Exports are increasing with 55 tons credited to December.

Ferro-silicon, 50%, is quoted at \$92.50 to \$95 per ton, delivered, depending on the quantity involved.

Ferro-chromium, 4 to 6% carbon, is quoted and has sold at 17c. per pound of contained chromium.

NOTES	277

THE PRICE OF SILVER.....	279
--------------------------	-----

The fluctuations in the price of silver as a guide to future movements. Wide price fluctuation occurred during 1920.

THE PRESIDENCY AND JOURNALISM.....	279
------------------------------------	-----

The remarks of a London contemporary on Mr. Harding's fitness for the position he is about to occupy. The administrative capacity of an editor. The distinction between an editor and a journalist.

TRANSPORTATION BY MOTOR-TRUCK	280
-------------------------------------	-----

Legislation is proposed for the purpose of restricting motor traffic over highways, on account of damage resulting. Many roads are badly built, and are easily ruined by heavy trucks. Dispassionate consideration of the subject is needed.

DISCUSSION

INSTITUTE AFFAIRS	281
-------------------------	-----

By A. W. Allen.....
The function of the many technical committees connected with the Institute. The value of 'Mining & Metallurgy' to mining engineers.

By A. B. Parsons.....	282
-----------------------	-----

The ethics of voluntary assessments. The irresponsibility of Institute officials in embarking upon new journalistic ventures.

MINING IN DUTCH GUIANA	283
------------------------------	-----

By Theo. F. Van Wagenen.....
A reply to a criticism made by A. P. Rogers in a previous issue, together with the information requested.

THE BROAD LODGE HYPOTHESIS	284
----------------------------------	-----

By L. S. Ropes.....
The advisability of the adoption of the square location and the 20-acre unit.

SILVER PRICES AND THE FAMINE IN CHINA	284
---	-----

By Thomas T. Read.....
A plea for the consideration of the effect of famine in China on the silver situation.

EDUCATING V. DROP-FORGING

By L. O. Howard.....	285
----------------------	-----

The curricula at mining engineering colleges, with particular reference to the study of the 'humanities'.

ARTICLES

ELEMENTARY FACTS ABOUT OIL	286
----------------------------------	-----

By P. B. McDonald.....
Vegetal and animal oils, bitumen, and petroleum. Scope for American capital abroad.

COPPER METAL FROM THE CONSUMERS' POINT OF VIEW	287
--	-----

Publicity methods to encourage the better appreciation of the value and uses of copper.

THE THEORY OF FLOTATION	291
-------------------------------	-----

By Reginald S. Dean.....
Formation of a froth. Inclusion of the ore-mineral in a froth. Effect of addition agents.

THE SAMPLING AND ESTIMATION OF QUICK-SILVER ORE	293
---	-----

By C. N. Schuette.....
General remarks on cinnabar deposits. Crude methods of sampling. Panning. Density of quick-silver ore.

INCOME-TAX RETURNS	296
--------------------------	-----

A comparison of income-tax returns for 1920 with those of the previous year.

THE LICENSING OF ENGINEERS.....	297
---------------------------------	-----

A bill introduced in the Montana legislature, with arguments for and against.

INDUSTRIAL PROGRESS	313
---------------------------	-----

Established May 24, 1860, as The Scientific Press; name changed October 30 of the same year to Mining and Scientific Press.
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bdg.; New York, 31 Nassau St.; London, 724 Salisbury House, E.C.
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$6; other countries, \$8.

Two miles of seamless copper tube a hundred feet underground!

The job illustrated—that of lining two miles of the Catskill Aqueduct with copper—shows in a compelling manner the extreme portability of

Prest-O-Lite

DISSOLVED ACETYLENE

Without gas—ideal for both welding and cutting—in such conveniently transportable containers—the oxy-acetylene process would lose much of its usefulness.

Whether the work be at the top of a sky-scraper or deep under the surface, in-

doors or out—Prest-O-Lite goes to the job!

A nation-wide service built around forty plants and warehouses insures a constant and prompt supply of Prest-O-Lite.

THE PREST-O-LITE COMPANY, Inc.

General Offices: Carbide and Carbon Building, 30 East 42nd Street, New York

Balfour Building

San Francisco

In Canada: Prest-O-Lite Co. of Canada, Limited, Toronto

T. A. RICKARD, Editor

OWING to an epidemic of smallpox in Montreal, the Canadian Institute of Mining and Metallurgy will hold its annual meeting at Ottawa, at the date previously announced, namely, March 2.

PRODUCTION of gold in the Transvaal last year decreased to 8,153,625 fine ounces, this total being the lowest since 1910. The record output was 9,296,618 ounces in 1916. However, although the quantity of gold produced on the Rand and in the smaller districts of the Transvaal showed a decline, the value of the output, thanks to the depreciation in sterling exchange, was £44,640,420 in 1920 as against £35,383,974 in 1919 and £39,489,522 in the best previous year, namely, 1916.

COPPER, as an industrial metal, is not properly appreciated by the public, more particularly the consumers, who have been beguiled into employing substitutes of inferior quality. That is the text of a speech delivered recently by Mr. Ivy L. Lee before the New York section of the Institute. We are glad to give Mr. Lee's speech in full in this issue because we are heartily in sympathy with his argument. We only marvel that the producers of copper should have delayed so long to commence this campaign of education in behalf of the beautiful red metal.

WE learn, from a consular report, that Poland has been negotiating for the purchase of 300,000 tons of nitrate per annum on a credit guaranteed by the Chilean government. If this arrangement is put into effect, a large part of the stock on hand will be disposed of. It is obviously a logical course to encourage an increase in yield from farming operations in Europe by the annual shipment of a comparatively small tonnage of fertilizer from Chile, rather than to attempt to solve the European problem by sending large amounts of food-stuffs, and, by so doing, to encourage idleness.

WE endeavor always to give credit where credit is due and, to this end, include a statement giving the names of operating officials in the summary of company reports we publish from time to time. The great majority of such reports fail to give this information; as it is not easy to obtain, there are delays in publication and we are liable to make errors. Accounts of mining and milling operations lose their significance and value when the names of the operating officials directly responsible

for the results are not given. We hope that the secretarial staffs of all mining companies will see that their reports are complete in this particular.

OUR 'Discussion' columns contain a letter from Mr. T. T. Read, on famine conditions in China, in which he forecasts far-reaching economic changes, unfavorable to silver producers, unless prompt assistance is rendered. Mr. Read knows China well, but we are inclined to be less pessimistic. Our consuls in foreign countries are generally well-informed as to local conditions, and from this source we learn that the unusually mild winter has helped to lessen the distress, and also that the relief measures in hand appear to be adequate to cope with the crisis. About 10,000,000 Chinese, in isolated districts covering an area no larger than the State of Pennsylvania, are affected—only about 2½% of China's total population. Commercial Attaché Julean Arnold cabled to Washington on February 9 that the American Red Cross and other relief institutions are handling the situation admirably, and that Chinese trade will not be appreciably injured nor Chinese credit affected by the famine. Although these reports are reassuring, it is obvious that the condition cannot be permanently improved without a considerable outlay. Those who are able and willing to help should get in touch with the American Red Cross.

GERMANY is regaining her place as an industrial nation. Her exports are increasing by leaps and bounds. England is being flooded with German goods, a large proportion of which are being sold as of British manufacture, for the storekeeper lacks the nerve to tell the truth about their origin. As before the War, German goods are much cheaper than those manufactured in Great Britain or the United States. German instruments of precision are finding a ready sale in England, because the Teutons are ahead of their competitors in design, ingenuity, and workmanship; they are content to work for long hours, while the victorious British laborer is "resting on his oars". We recently examined a sample of German post-war workmanship—a pocket camera—a remarkably compact and complete piece of apparatus, of exquisite finish. Fitted with the well-known Zeiss lens, this camera fetches a high price in England, where it meets with no competition from any British-made article of the same type. As a Government official has stated: "Germany is still a perfect industrial machine, running at low speed it is true, but undamaged as yet in

its vital parts;" she will yet show the world that "peace hath her victories, no less renowned than war".

CONDITIONS in Mexico are described by Mr. William G. McAdoo, who has just been there, as "better than at any time since the revolution began ten years ago". In an interview he says that there is evidence on every hand of a return to peaceful activity and of renewed industrial progress. He met President Obregon and was most favorably impressed by his "fine common sense, great sincerity, and full comprehension of the serious problems confronting Mexico", one of which is the rehabilitation of the national credit. Mr. McAdoo lays stress on Mexico's dependence upon foreign capital for the development of her vast natural resources and suggests that "the only available market for capital and credit is the United States", wherefore it is essential that a good understanding be established with our country and with our Government. All those interested in mining in Mexico will look forward to the fulfilment of these friendly hopes; for ourselves, we feel that the de facto government has justified itself to a degree that demands official recognition from Washington, and we hope that such financial aid as is needed will be forthcoming as an evidence of our faith in the future of Mexico.

TISDALE township in Ontario levied a tax upon the reduction plants of several mining companies operating in the Porcupine district of Ontario, Canada. They claimed exemption on the ground that their mills were 'concentrators'. The question of liability to this taxation has gone through three courts, namely, the Court of Revision, the District Court, and the Appellate Division of the Supreme Court of Ontario. The first and the last of these decided in favor of exempting the mining companies from the tax under the Sub-section 4 of Section 40 of the Ontario Assessment Act. The gist of the decision, according to our friend the 'Canadian Mining Journal', is that "the term 'concentrator' is a term loosely applied by technical men to various kinds of mills in various localities, and is not a rigid term of fact having a strictly defined signification, and that a mill of the kind in question on these appeals is not disentitled to be termed a concentrator by reason of its combining chemical processes—the amalgamating or cyaniding, or both—with mechanical apparatus in separating values from mineral-bearing ore". If the mental processes of those responsible for this opinion are no better than the phraseology they adopt, we can have little confidence in them. One might as well exorcize the indigestibility from a doughnut as separate the values from a mineral-bearing ore. Is there such a thing as a non-mineral-bearing ore? Our contemporary, whom we have quoted, interprets the decision as meaning that "any part of the process of extraction of gold bullion from the native ore, or gold-bearing rock, is covered by the term concentration". If that be so, then the sale of stock in a mine by the promoter of it is a process of concentration whereby the gold in the pockets of the many is brought into the

pockets of the few. To 'concentrate' is to bring together to a central point; to increase the strength of anything by contracting its volume. To concentrate an ore is to bring together the valuable particles of mineral into a product so much less voluminous as to cheapen any further metallurgical treatment. It does not involve a change in the mineral by a chemical process, only segregation into smaller bulk. However loosely the term 'concentrator' may be used by technical persons, it does not connote the use of leaching or other chemical processes; on the contrary, it is restricted to the crushing, grinding, sizing, and bringing together, by mechanical means, of the desired parts of an ore while rejecting those not desired. The Appellate Division of the Supreme Court of Ontario has been fooled.

THE story of the Congressional junketing to China, Korea, and Japan has just been received. It consists of a special issue of 22 pages of the 'Congressional Record', reporting the speech of the Hon. Henry Z. Osborne, of California, in the House of Representatives on December 23 last. This priceless document arrived enclosed in a specially printed and sealed envelope, decorated with a facsimile of the gentleman's picturesque signature. The skill with which the accredited spokesman of the picnic switches from the business in hand before the House—the Pension Appropriation Bill—is worthy of note. "Our country", he was saying, "has in all its history been thoughtful and tender of those who have bared their breasts to the storms of war, who have taken their lives in their hands for their country, and it is well that this should be so. It is not, however, my intention to speak upon the subject of this bill further than I have already done. During the summer just past a number of members of this House and certain members of the Senate made a trip to the Orient", and then comes the picnic story, relieved at intervals by sub-headings such as "A Great Day at Hangchow", "Sight Seeing in Peking", "A Sunday at the Seashore", "Shooting the Hodzu Rapids", "A Regular Japanese Dinner", and similar ticklers to sustain interest. The House had listened to the account for about an hour when the honorable gentleman was advised that his time had expired. Having explained that he had only just begun, he was granted an additional half-hour in which to continue the recital. At its conclusion he was again reminded that there was other business before the House, but a further extension of time was made. After this no attempt was made to induce him to desist. The legislators, whom the daily press labels 'solons', learned the most intimate details of the pleasure cruise, and the honorable gentleman was allowed to continue his yarn to the bitter end—to the last day when, having been entertained royally on all sides and having seen all there was to see, Mr. Osborne spoke to a number of representative Japanese on the Californian question, and "with entire frankness", the result being that "some of our Japanese friends shed tears on saying good-bye". Crocodile tears, we venture to suggest, and not of the variety that many among us would be inclined to shed at the

thought of such official waste of time and opportunity in the House of Representatives, and of good money squandered in the printing, proof-reading, and distributing of a florid account of an excursion taken at the expense of the taxpayers. Mr. Osborne and his friends have 'put one over'; the publication and distribution of the account of their picnic 'rubs it in'.

The Price of Silver

When the market for a particular commodity is depressed it is wise to study the history of past fluctuations in order to obtain an inkling of the future course of prices. A glance at the record of the silver market may serve to hearten some of our friends who are in the dumps just now. We give herewith a chart showing the rise and fall of silver quotations during the last half-century and also during the last five years. It will be

CHART SHOWING FLUCTUATIONS IN THE PRICE OF SILVER

noted that the points on the 'curve', as such jagged graphs are termed, represent the average price during the periods considered; thus the 1919 peak on the annual record is just above \$1.10, whereas in the bi-monthly record the peak is above \$1.31, this last representing the average for the months of January and February 1920. The annual record descends for 1920 because of the great decline during the latter part of last year. The highest price during late years for any one day was \$1.37 on January 13, 1920, whereas the lowest price was 59½ cents on December 10, 1920; thus in one year the market showed an extreme difference of 77½ cents per ounce, greatly to the perturbation of those engaged in the mining of silver ores. Since the beginning of the current year, a new low record has been made, the price receding to 58½ cents on February 18. All this refers, of course, to the international market for silver and not to the market for American silver, which has been stabilized at \$1 per ounce since the Pittman Act went into effect in June 1920. Returning to the bi-monthly averages, it will be noted how uniform was the rise during the four years after the slump in 1915, when the annual average was 50 cents, although on September 1, 1915, the price

reached 46½ cents, the lowest ever recorded. Taking the longer period, 1865 to 1920, it is evident that the average price was about 90 cents per ounce, which is slightly above the average for the last five years.

The Presidency and Journalism

The London 'Spectator', an exponent of sober British thought and the successor of the paper immortalized by Addison and Steele, speaking of President-elect Harding, mentions "one's pride in seeing a member of one's own particular profession rise to the occupation of as high a post in government as the world has to offer". We share that pride, although the frequent use of the impersonal pronoun would not come as naturally to us as to the editor of the 'Spectator'. He proceeds to say that "a journalistic training is a very good one for a President or Prime Minister", and the President of the United

States is both. A journalist may be superficial, but so under modern conditions is any man who must give daily a dozen decisions on matters of first-class importance, as the President is compelled to do. "In an humbler way", says our respected contemporary, "this is exactly what a newspaper editor is constantly called upon to do. He is always having to take a line, very often to take it suddenly, and generally to take it on what is possibly imperfect information." Yes, indeed, the President must be a good deal like an editor, and having been one Mr. Harding will be prepared to face the music. "Appalling as it must at first seem, even to a journalist, to give decisions such as those a President must give daily, the matter is not half as overwhelming to him as it must be to a man without the journalistic training who is suddenly put into the highest office in the country. The President of the United States may be called upon in one and the same morning to give decisions which involve problems of currency, the rights and wrongs of Bolshevism, the Yellow Peril, the Negro Problem, the problem of the big Navy or small Navy, and so forth and so on. To most men these problems would be a nightmare. To the veteran journalist they are old friends." The gen-

tleman of 'The Spectator' evidently is sympathetic, a quality needed by editors in order to give them a wide interest in the affairs of men, but he makes a curious error in identifying the 'journalist' with the 'editor'. An editor is usually a journalist but every journalist is not, and has not the qualities fitting him to be, an editor. The latter is responsible for the policy of his paper, whereas the journalist is responsible only to himself, and can pass much of that responsibility to the editor who accepts his writings for publication. Mr. Harding has been both journalist and editor, so he has had experience both in making up his mind quickly on diverse subjects and in exercising the responsibility of giving utterance to the opinion of himself and of others. This ought to help him in the Presidential chair and it ought to bespeak for him the sympathetic consideration and friendly support of every editor.

Transportation by Motor-Truck

Legislation for the purpose of limiting the size of motor-trucks that may be operated over highways has been passed by a number of States in which the roads are said to be in danger of being ruined by heavy traffic. The result has been that manufacturers of trucks have launched enthusiastic propaganda intended to hinder the passage of further bills and to effect the repeal of those already on the statute-books. We concur in large part with the views of those interested in haulage by motor, but we venture to suggest that some of the literature being scattered broadcast would be more effective if it were not quite so violent in tone. Some of the arguments seem to appeal more to self-interest than to reason, whereas of reasonable argument there is plenty. The declaration that "the motor-transport industry must not be ham-strung by iniquitous regulation", because the burden will finally fall upon the "ultimate consumer", in the shape of increased cost of finished products, is too trite; it savors of insincerity. Grave concern for the unhappy consumer is too often prompted by an anxiety as to one's own financial welfare. The immense size of the industry of motor transportation is rightly emphasized; about 900,000 trucks are engaged in hauling sundry kinds of freight in the United States with a considerable reduction in cost over former methods of performing the same work. The special field for the motor-truck is the 'short-haul', and for such work it is welcomed by the railroads; although there is doubtless an intermediate zone within which the railroad and the motor-truck compete. It is contended that on hauls up to 175 miles the 1½-ton motor offers more economical transportation than the railroads, provided fairly good roads are available. The maximum radius for a 6-ton truck is about 350 miles. The greater ultimate efficiency of the heavier truck is indicated by the comparative cost, including depreciation, labor, and maintenance, for operating machines of different sizes. Reliable data show that, whereas under favorable conditions a 1½-ton truck can move freight at an average cost of 17 cents per ton-mile, a 3-ton truck can do equivalent work at a cost of

12 cents, and a 7-ton machine can duplicate the performance for approximately 7 cents. The increased efficiency of the truck as compared with the railroad arises largely from the fewer number of times freight must be handled when either the point of origin, the destination, or both are not on a railroad spur or side-track. Motor-haulage is particularly successful in the mining industry. Many valuable properties, situated at a distance from a railway, do not promise traffic of sufficient volume to warrant the construction of branch lines. Under such circumstances a well-built highway and a fleet of trucks frequently affords the ideal means for hauling supplies to the mine and the products of the mine back to the railroad. As compared with teams, which offer the only alternative, the advantage is always in favor of the truck, provided a road can be built on a reasonably moderate grade. The investment is greater if trucks are used, but the gross cost per ton-mile will be much in favor of motor-haulage. Trucks, both large and small, are used to excellent advantage at many mines for moving machinery, cement, gravel, timber, and other heavy supplies from place to place on the property. However, the admitted utility of the truck is not of itself a valid argument for permitting excessively heavy machines to ruin the public roads. The scientific opponents to the prohibition of large trucks have endeavored to prove that size is not the factor determining the amount of wear on the road. Tests conducted by the U. S. Bureau of Public Roads indicate that impact of the wheel, rather than the gross weight of the loaded truck, does the damage. In other words, the 'unsprung' weight must be minimized; this weight depends in part on the design of the individual machine, and the ill effect is mitigated to a large extent by the substitution of pneumatic for solid-rubber tires. It is obvious that steel tires, so frequently used for loaded trailers, have no place on any highway. It has also been demonstrated that a normally loaded 3-ton truck operated at 20 miles per hour will do more toward destroying a road than a similar 7½-ton vehicle traveling at 10 miles per hour, which suggests another direction for regulative action. Few of our roads were built to withstand the traffic of heavy and rapidly moving loads; the strain has been too great, and the road-bed, not the surface, has given way. It is said that 70% of the trouble has arisen as a result of defective drainage and weak subsoil. Some of the roads being built at the present time are constructed scientifically with adequate sub-grades, built to withstand the passage of loaded trucks. Unfortunately, however, politics is mixed with road-building, the result being an effort to build two miles of road for the price of one. The surface is handsome; the foundation does not show, and is therefore given scant attention. Eventually there should be a system of good roads connecting all important points; in the meantime we commend a reasonable compromise between the enthusiasts who object to any regulation or limitation, and the zealous law-makers who see no way to preserve the roads other than by prohibiting the heavier trucks under any and all conditions.

DISCUSSION

Institute Affairs

The Editor:

Sir—I venture to suggest that the lamentable condition of the finances of the Institute may be traceable, to a considerable extent, to a cause to which little attention has been paid. The directory contains the names of over 400 members who serve on over 40 committees and sub-committees. The list includes a number of eminent men, whose professional status and wide experience is beyond question. The names of others are unknown to me. Several of the committees have been appointed “to obtain papers of high merit for publication by the Institute”. As a member, I would be glad to know how these committees are formed. By whom are they chosen? It appears to me that they have, in many instances, failed in their duties.

I attended the New York meeting in February 1919; and being especially interested in milling methods I hoped to glean something of worth in the discussion of a paper on ‘Fine Crushing in Ball-Mills’. The subject was a live one. The application of the ball-mill to modern ore-dressing work involves vast expenditures; therefore research that would lead to the introduction of even trifling economies would be welcome. Although some misapprehension with regard to ball-milling had been cleared away, the lack of definite conclusions, which should be easily obtainable and which would establish the superiority of certain types of mills for certain work, was evident. The facilities at many of the university experiment stations appeared to me to be such that valuable data would result from impartially conducted research along practical lines.

As an effort to elucidate any of the problems of ball-mill work the paper itself had been a distinct disappointment. A title such as ‘Fine Crushing in Ball-Mills’ inferred a broad treatment of the subject, incompatible with the fact that the tests were made with, and the results only applicable to, a single type of conical mill. By not correcting the title the committee encouraged the idea that a mill of special design could be used to determine data on ball-milling in general, and so ensured the shelving of one of the most important questions yet to be determined, namely, the comparative efficiency of ball-mills of different shapes.

The paper consisted of 46 pages of matter. Much of this was in the form of an imposing array of complicated and involved mathematical calculations, which must have appeared to an engineer to be of little or no practical significance. The author of the paper unconsciously con-

firmed this conviction when, after an illuminating display of theoretical reasoning on the question of ball-mill speed, he naively added that: “In actual practice it may be found that more effective crushing can be done at some other speed”!

In order to emphasize the unusual nature of some of the work given publicity, attention may be drawn to the fact that the ‘problem’ was to crush a comparatively fine gravel (minus $\frac{1}{4}$ in.) to 200-mesh, and for this purpose a mill of 8-ft. diameter was chosen. In the first test described a load of 14 tons of steel balls of 5 in. diameter and smaller were used to grind a feed of 3.66 tons per hour. The result of this test was that 2.24 tons of 200-mesh material was “actually produced”. The feed was then increased and the usual chart drawn. For reasons that no ordinary enthusiast could appreciate, the tests were stopped when a feed of 18 tons per hour had been reached. The author’s comments were illuminating: “. . . the tonnage of 200-mesh material produced varies directly with the tonnage fed to the mill. There is undoubtedly some limit to this relation, but there seems to be no indication of it at 18 tons per hour. Some of the conclusions drawn from the test are”, we were told, “(a) the ball-mill is naturally a machine with a very large capacity; (b) if it is not possible to deliver a large tonnage of original feed to the mill, a closed circuit should be provided . . .”

The “conclusions” left me gasping. The first I classed among milling platitudes; and, as regards the second, one naturally asks: “If it is possible to deliver a large tonnage of original feed to the mill—and what is there usually to prevent it—what then?” And this is the result of a test “to determine the crushing efficiency of the ball-mill operating in open circuit”! There was no discussion at the meeting—those present with a knowledge of ball-milling were speechless apparently. The ‘Milling Methods’ committee consists of over 60 members. Is it really a committee; and do the members, collectively or individually, use their judgment in these matters? Do they insist on brevity, and do they point out to intending contributors the necessity of commencing their investigations where others have left off?

A few years ago an engineer of wide experience and some standing in the profession took up his residence in New York. Being a member of the Institute, a specialist and a writer in a particular branch of metallurgy, he courteously placed himself at the disposal of the chairman of the special committee on that subject. A formal acknowledgment of the offer was received, and there the matter ended. The committee was duly ‘picked’. About

60% of those nominated were, according to their designations in the directory, not specialists; several were unknown as having contributed in any way to the technology of the subject. Two members of the committee were connected with a commercial undertaking vitally interested in the sale of machinery in that particular field; these could not be expected to give an impartial decision; although as a *quid pro quo* for a certain amount of advertising in the Institute's magazine their appointment to the committee was doubtless sound business policy. We need more limelight on the precise methods adopted in appointing committees of this nature. As a subordinate trustee of some of the money paid in dues, such a committee should be selected on the basis of special qualification; and, having accepted the nomination, every member should realize that the position carries obligations as well as honors.

After several years of membership of the Institute I have to go to a library to consult the Transactions. Owing to the high cost of rent and the levies on excess baggage I have been obliged to throw away my copies of the proceedings as received. Mining engineers would fain reduce their books of reference to small compass, but in this one instance they must take all or none. With regard to the publication of the monthly magazine, I am in entire accord with those who favor its early decease. A mining engineer of high standing on the Pacific Coast, in discussing this question with me recently, said that because of the necessity of keeping in close touch with all phases of development in the application of mining and metallurgical methods he followed a plan of scanning all publications as received, marking those articles which deserved detailed study or which should be filed. To him, as to many others, 'Mining and Metallurgy', as a source of information, has proved barren. It is worse than useless, for much time and labor is spent, and temper is occasionally lost, in the search for what is never there.

I suggest the election of advisory committees pledged to see that the publications of the Institute are condensed, by proper editing if necessary, to a reasonable bulk, or by the exclusion of the obvious, the absurd, and the uninformative.

A. W. ALLEN.

San Francisco, February 10.

The Editor:

Sir—The following points appeal to me, as a member of the Institute, as being pertinent to the discussion precipitated by the recent 'voluntary' assessment of \$10. In spite of the recent definite trend toward its enhanced importance in the task of making ends meet, a 'ten-spot' is still a small item. Nevertheless sensible engineers as well as business men are asking themselves today whether or not they are approaching, within reasonable limits, the maximum efficiency in even the smallest expenditures. It is the privilege of each member to inquire whether the funds of the Institute are spent effectively and economically; and he is further concerned in the question of whether or not he is getting just what he wants from the

Institute. In the end his expenditure is just as inefficient if he gets a product that is of no use to him, even though the operation of preparing that product be in itself 100% efficient, as if the actual process of production were wastefully performed. To many the mere fact that a deficit impends suggests the possibility of inefficiency or indifference somewhere in the administrative organization. Moreover, the recent assessment and the accompanying explanation are far from reassuring. In the first place, the deficit is given as approximately \$20,000, whereas \$10 collected from each of 9446 members would amount to \$94,460, thereby leaving a surplus of some \$75,000. Doubtless it was suspected that some would decline to pay; apparently then to make sure of having enough, \$10 was decided upon as a convenient amount. It is fair to say that this haphazard method of financing seems ill advised and that it is not calculated to gain the confidence of the members in the competence of the business administration.

The method of procedure is open to criticism from another point of view. A few doubtless paid without giving the matter a second thought; a good many considered the matter and decided to pay with a feeling of resentment because they felt slightly imposed upon in paying four times their fair share; and many concluded, as a matter of principle, not to pay, in spite of a decidedly uncomfortable feeling that their share was being paid by some other member. The average member guards jealously the privilege of 'holding up his own end'; but at the same time he dislikes to feel that advantage is being taken of his desire to do the square thing. If the required amount had been pro-rated among all the members, I venture to say that there would have been few delinquents and a great deal less hard feeling.

The statement made by the directors offers the explanation that the deficit arises because it is deemed unwise to curtail the activities of the Institute. It seems evident, however, that the plan of publishing 'Mining and Metallurgy' was launched at a time when the finances of the Institute were in a parlous state. Anyone with the experience in publishing that Secretary Stoughton has had must have known that the enterprise would be costly, and presumably he advised the directors of the fact. A great many members feel that the magazine in its present elaborate form is entirely outside the province of the Institute; but whether it is desirable or not, it is reasonable to enquire why its publication was authorized when a financial deficit was likely to ensue. The whole thing suggests a laxness or dissipation of administrative responsibility that is at least open to investigation.

Volume LXII of the Transactions, containing some 800 pages, was devoted to papers relating to the iron and steel industry, most of them discussing sundry phases of specialized processes, none of which are of the most remote interest to the 'non-ferrous' metallurgist or the average mining engineer. Is this symptomatic of a lack of discrimination in choosing the material to be printed in the Transactions? Should they be made a record of

exhaustive researches on subjects of value or interest to not more than a few dozen members, excellent though the papers themselves may be? Or should the policy be to publish only the best articles dealing with real progress in the arts and sciences connected with mining and metallurgy.

The main issue, of course, is not the payment or non-payment of the \$10 assessment. That is a mere incident. The question is whether or not, in the effort to increase membership and to gain public influence and prestige, the basic purpose of advancing the profession as a profession has not been submerged. In this connection it may be pointed out that the organization of the Federated American Engineering Societies, of which the Insti-

knows of its whereabouts. But here is a photograph of one there that is over 200 ft. wide, that has been worked to that width and to an equal length along its course. This, in short, is the open excavation that has yielded the 60,000 tons of ore from which \$135,000 has been recovered by plate amalgamation only. Everything in sight is payable ore, in the floor, in the face (which is about 100 ft. high) and on both sides, for in neither direction have unpayable boundaries to the body yet been reached. There is no waste-dump. All material broken has gone through the mill. Below the latter is the tailing, which has been demonstrated by hundreds of tests to contain better than \$1.50 per ton. Ahead of the excavation and along the line of the orebody scores of pits and open-cuts

THE TEATS QUARRY IN DUTCH GUIANA

tute is a member, has undertaken to concentrate and direct the energy and influence of the engineers of the country with respect to social, industrial, and political problems, thereby leaving the individual societies to perform their primary function, which has to do with progress in technical and scientific affairs.

San Francisco, February 11.

A. B. PARSONS.

Mining in Dutch Guiana

The Editor:

Sir—Mr. Rogers' letter in your issue of January 29 is interesting. Though he claims to hail from New York, he displays the Missouri temperament, and evidently wants "to be shown". All right! I will try to enlighten him.

The two-foot vein of \$2.50 ore which he discovered at the time of his visit, and which no one previously had noticed, has apparently been lost since then. No one

have been dug upon it for a distance of over a mile, and all of them exhibit the same character and quality of material as has been taken from the quarry. This means at least eight million tons above the floor and probably much more, for the mineralized zone has a width in place on the surface of 1200 ft. Right at the quarry it is 500 ft. wide.

As to the profits of the undertaking, it is sufficient to say that the owner of the property has invested no capital in it. It has paid for and equipped itself from the start and has yielded a surplus over all costs. It is not for sale.

As to climate and sanitary conditions, it is perhaps possible to find a few places on the planet with a death-rate of less than 14 per thousand, but not many. And why should one become excited over an annual precipitation of 80 inches? In the Scotch coal and iron districts the rainfall rises to 130 inches, but they manage to keep the water out of the shafts, or to pump out what slips in.

The experience at Panama proved that the West Indian black laborer, when properly handled, fully earns his small wage. The Surinam negro workman is of the same racial stock; he will do better than the average Mexican peon in Mexico.

It is five years or more since Mr. Rogers was in Dutch Guiana. Much can happen in a period of that length. It is rather unusual to condemn a region on the basis of observations made so long ago.

Denver, February 4.

THEO. F. VAN WAGENEN.

[This gives us the opportunity to correct a typographic error made in the printing of the letter from Mr. Rogers. His correct initials, as is well known, are A. P., not A. R. —EDITOR.]

The Broad Lode Hypothesis

The Editor:

Sir—In your issue of January 29, Mr. F. L. Sizer enters the discussion on the Utah Consolidated v. Utah Apex law-suit, which has aroused more interest in the hypothesis of a broad lode than any previous litigation within my recollection.

The suggestion in the last paragraph of Mr. Sizer's letter ("The only real cure for the evil of apex litigation will be the adoption of the square location") is in line with suggestions made by me, while in the Government service and at various other times. I am glad to see this phase so opportunely injected into the discussion, as it is evident that there is pending the introduction of a bill in substitution for H. R. 12275, February 25, 1916, legislation looking to a revision of "Sections of the Revised Statutes of the United States relating to the location of mining claims on the public domain, and for other purposes." The less said of the above mentioned H. R. the better.

In somewhat more detail, I would suggest that the 20-acre unit, lode or placer claim, be retained; that where the public lands have been surveyed, these units conform to the public-land surveys or half of the 40-acre legal subdivision, north-south or east-west, as best suits the strike of the lode or the course of the gulch, as the case may be; that, the dip of the lode, inferred or disclosed, be protected by locations made to cover same, in lode mining, off the dip from the apex claim. It may be desirable to limit such, protecting locations to one, two, three, or more, parallel claims, the number to be regulated by the dip of the lode or deposit.

These locations would be bounded by vertical planes on all sides. Precedent for such suggestions is found in the older settled sections of the country in which the mineral land laws do not apply. For instance, the Lake Superior iron and copper mines, would, had they been located under Western mining laws, have afforded some perplexing legal problems, even more so, I believe, than the most perplexing yet brought to court in the West. It would be interesting to look into the situation as bearing on some of the iron deposits of the Gogebie iron range of Michigan and Wisconsin. The copper mines of Michigan

afford the suggested necessity for "three or more" protecting locations "off the dip". There, with the dip of the "beds" at 35° to 40°, the mines have been worked to depths of 8000 ft. on the dip.

In the West, Bisbee operators took the bull by the horns. Have we any long-drawn expensive apex litigation coming from that famous copper district?

Revision of the mining laws is imperative; it is vital to the development of the mineral resources of the West. Present locations and patents could be adapted to the proposed plan, in a majority of cases, where intervening locations are not involved.

The present rules and regulations of the General Land Office are breeding dissension, quarrels, and law-suits, owing to the permitting of agricultural entries on classified mineral-lands, in fact, such are well under way in this State. That it has not become more pronounced is due to the lethargy of the mineral industry for the past several years, and, in the case of Montana, to the boosting of "dry-land farming", advertising by the railroads, the land agents, and the press, along agricultural lines. The drought of the past three or four years has had a discouraging effect on such agricultural entries, however, and, in the draughting of new mineral-land laws this situation should be fully considered and the disposition of the lands so provided for as to prevent the clashing of varied interests.

With the turn the discussion has taken, the Utah Consolidated v. Utah Apex case may be of everlasting service to the prospectors, operators, and investors of Western mining enterprises.

L. S. ROPES.

Helena, Montana, February 3.

Silver Prices and the Famine in China

The Editor:

Sir—The relation between the probable future price of silver and the widespread and serious famine that exists now in five provinces of Northern China may not be evident at first glance, but a very real relationship does exist.

China and India have always been the parts of the world that absorb silver with almost the avidity with which a sponge takes up water; therefore the social conditions in these countries have a marked effect on the price of silver. In its efforts to stabilize the value of the rupee, the Indian government has accumulated a large stock of silver, and it would appear that China must be the mainstay of the silver market, for the immediate future at least.

Unfortunately, from the unusual series of crop failures, five provinces of Northern China, having a total of nearly 90,000,000 population, are in the grip of the greatest famine ever known. More than one-half the people of these provinces are seriously affected and it is estimated that some 15,000,000 will die unless food is furnished them. The humanitarian appeal to help the suffering is so evident that I do not need to refer to it, but, I should like to point out that the desirability of render-

ing aid, so far as we can, might be looked upon as wise business foresight as well. If the people in this immense area are so weakened by starvation that they are unable to plant crops this year, presumably famine conditions will be even more widespread next year and the whole of Northern China will be impoverished.

The railways of China have outstanding over \$300,000,000 worth of bonds, most of which are held by foreign investors. If, as a result of the conditions now existing, business so declines that the railroads will not earn interest on their indebtedness, the security of these investments will be threatened and it is obvious that in general the buying power of China, and consequently its support of the silver market, will be greatly decreased.

I beg to make the suggestion, therefore, that silver producers would do well to realize that they have an interest in the problem of furnishing aid to the famine areas in China.

THOMAS T. READ.

Washington, February 11.

Educating v. Drop-Forging

The Editor:

Sir—I have read with some interest Mr. Coghill's article on this subject. Since you have devoted space to editorial comment upon it, I assume you welcome further discussion.

You are wholly right regarding the inadequacy of the criteria submitted, for there is no question but that at the time the men to whom Mr. Coghill refers graduated from college, the mining curricula at both institutions, mentioned by name, was quite similar to that of most other mining schools. I do not believe that these men, in particular, were compelled to be 'educated', but could just as easily have been 'drop-forged' had that been their tendency. I confess I do not see the reason for selecting just one Eastern school as an example of all of them. That is the only one, to the best of my knowledge, that requires an undergraduate course before admission to the School of Mines. The others educate men also without this requirement. In fact, I believe both the Massachusetts Institute of Technology and Harvard used a similar plan at one time, but have since abandoned it.

Those of us who have given much attention and real thought to mining education know that it is directly up to the student, and that in the mining schools of the West, particularly in the North-West, there is nothing to prevent the student from acquiring as many of the 'humanities' as he wishes, as well as the prescribed course if he has the time and money for it. I venture to say that no Eastern schools offer a broader four-year program than those offered here in the North-West. Further, it is a fact that toward the end of the first decade of the 20th century the four-year program was standard in the East, and today but one school requires anything different. At the State College of Washington, which may be taken as typical of Western schools in general, the student has a definite program to complete in four years, in which an endeavor is made to include some of the cultural subjects.

The student may, if he wishes, here as elsewhere, spend five or six years, as in the East, and devote all his additional time to the so-called cultural subjects. No school of mines, however, is warranted in compelling him to take this extra time. Many men would be deprived of the opportunity of valuable education were they compelled to spend six years in getting it. The student is usually more or less mature upon matriculation. He may justly ask that he be allowed to complete his courses in four years if he so wishes. Mining education would be in sore straits indeed were all men, regardless of age, ambition, or opportunity, cut to the same six years' course.

In the case of the schools referred to as "isolated", I am certain that there are great universities near-by where the students might take a preliminary course if they so desired. 'Drop-forging' is not then a function of East or West. 'Who's Who' or 'Who's Not' may be found in as many of the institutions in the East as in the West. This does not mean that the major subjects must not be taught in such a way as to educate properly, but my point is that many men become a credit to their profession who take the regular four-year courses in our schools of mines, be they located in the East or the West. It is undoubtedly true that it may benefit a man to remain longer at college.

I feel just as much concerned as Mr. Coghill about too much of an attempt to 'drop-forge' men, to use his own expression, but I do not feel that this is inherent in our Western schools of mines, and I think that a complete investigation by Mr. Coghill would have shown the same to him, although for students who can afford five or six years in college we would most heartily recommend part of an academic course before taking up the major subjects in mining, but this does not imply that no one should be allowed to take the straight four-year course, or that Western mining schools should be abolished, because they do offer such a course.

L. O. HOWARD.

Pullman, Washington, February 8.

Tin Exports From Malaya

The total tin ore exported from the Malay Peninsula in 1919, according to a consular report, amounted to 741,970 piculs valued at \$32,247,444, compared with 768,157 piculs in 1918 valued at \$41,623,383. The following table indicates the movements of Straits tin shipments since 1910, quantities being expressed in tons of 2240 lb. each:

Years	United Kingdom	United States	Continental Europe	Total
1910	35,047	12,915	6,643	54,605
1911	35,505	15,375	6,288	55,168
1912	33,482	18,238	7,230	58,950
1913	35,158	18,107	9,105	62,370
1914	35,652	19,240	9,308	63,198
1915	22,753	32,240	11,006	65,999
1916	25,011	28,108	8,481	61,600
1917	16,304	13,457	6,190	*35,951
1918	(+)	(+)	(+)	(+)
1919	19,592	27,135	4,111	50,838

*January to June, inclusive.

†No official records available owing to Government restrictions on publications of trade returns.

The picul is an Oriental commercial weight of 133½ lb. in the Straits Settlements, and 140 lb. in the Philippines.

Elementary Facts About Oil

By P. B. McDonald

The attention being paid to oil, in connection with industrial and international affairs, makes it appropriate to recall sundry elementary facts of which engineers who have specialized in metals have, perhaps, a hazy conception. Webster says that oil belongs to a large class of unctuous combustible substances that are liquid, or easily liquefiable on warming, and soluble in ether but not in water. An essay on oil by Sir E. Ray Lankester has been included in 'Secrets of Earth and Sea', published by the Macmillan Company.

Sir Ray remarks that mineral oils and waxes possess a great advantage over vegetal and animal oils in that they do not become rancid; they do not decompose as a result of the action of bacteria. A further difference between the paraffines and the vegetal and animal fats is that the paraffines do not combine with alkalies and other bases to form soap; nor can they serve as food for man or animal, because they are not acted upon by the digestive juices. These facts, of course, are known to the Standard Oil Co., which makes and sells a preparation called 'Nujol', but perhaps they had escaped the attention of the average engineer not especially informed on matters relating to characteristics of oils.

Natural bitumen, as the Romans called it, has been known and used from ancient times. The term, in its widest sense, includes natural gas, the various petroleum, and solid asphalt. The Egyptians used asphalt for embalming their dead; the ancient Assyrians used it ('slime' in the English version of the Bible) in place of calcareous mortar for building; and in Europe today it is used as a 'damp course' in walls built of brick. In addition to the famous lake of pitch on the island of Trinidad, there is a rich deposit in Switzerland, from which the asphalt used for making roads is obtained. Harry Franck, in his recent book on the West Indies, describes the simple way in which asphalt is dug from the firm surface of the 'lake' in Trinidad, and how by next morning the excavation is again filled.

The ancients noticed natural springs of liquid bitumen (petroleum), some flowing freely like water, that would take fire and burn for long periods, and were described as fountains of "burning water". The Greek word for naphtha was applied in early times to petroleum issuing from the ground in South Russia and Persia, in which regions today are to be found some of the world's most important oil-wells. The term 'naphtha' is still applied to the more volatile hydrocarbons obtained by the distillation of petroleum, coal-tar, wood, and shale. During the Middle Ages and the period of exploration that followed, records were made of springs of inflammable oil in Japan, China, Burma, Galicia, Italy, England, and Central and North America. Mineral oil, until the middle of the 19th century, was valued chiefly as a medicinal application, 'Seneca oil' and 'American medicinal oil' being widely sold as an embrocation. This, of course, was before the time of the great John D. Rockefeller, and

when whale oil, relied upon for illuminating purposes, was comparatively expensive.

The name 'petroleum' was introduced by Professor Silliman in 1855, when he reported upon the 'rock oil' or 'petroleum' of Venango county, Pennsylvania. The Pennsylvania Rock Oil Co. bored for oil in 1854; and after several unsuccessful attempts the tools dropped into a subterranean cavity at a depth of 69 ft. On the following day the well was found to have struck oil, with a yield of 25 bbl. per day. Even so late as the year 1900 only 64,000,000 bbl. was produced in this country, a trivial amount as compared with the 250,000,000 bbl. of annual production in recent years.

The early prejudice against the use of petroleum as an illuminant was due to its offensive odor, which perhaps gives emphasis to the theory of a fish origin advanced by some geologists. The ancient Romans burned petroleum from Sicily as an illuminant, but perhaps their sense of smell was not so sensitive as that of our people. Petroleum was discovered on the western slopes of the Alleghanies in the early part of the 18th century, during the boring of brine-wells, but it remained for a Dr. Brewer, in 1853, to suggest its use as an illuminant and to develop a method of purifying it.

Oil has become so significant a factor in economic calculations that governments are debating how to outwit one another in capturing the world's output. If, as Herbert Hoover advocates, American capital should seek permanent outlet abroad to offset the inequalities affecting our balance of trade with some foreign countries, it would seem that speculation in oil properties would offer an excellent field.

Repairing Iron Vats

A method of repairing cyanide vats that deserves a wider publicity is described by C. Flury, in a recent issue of the 'Journal of Industrial & Engineering Chemistry'. The bottom of a 5.5-ft. by 22-ft. leaching-vat contained numerous holes, and some parts were so badly worn that a needle could be passed through without effort.

At first the leaks were caulked with coal-tar-soaked cotton waste, a method which proved to be inefficient. Then a 2-in. cement bottom was laid on the inside of the vat; but pressure variations during charging and discharging, causing bendings of the bottom, broke the cement layer. This observation led to the construction of a more flexible bottom, built as follows: Over the whole defective bottom was laid a 0.25-in. asphalt layer, covered with canvas which consisted, in this case, of old filter leaves. Care was taken that the canvas was pressed on the asphalt while the latter was still hot, in order to secure a close contact. Finally the canvas was covered with asphalt for a thickness of 0.25 inch.

After 24 hours the vat was filled with water, held under water-pressure for 72 hours, discharged, filled again, and held under pressure again for 72 hours. During this test not the slightest leak could be observed. The total repair cost amounted to about \$92.

Copper Metal From the Consumer's Point of View

*During the 25 years between 1895 and 1920, the most notable period in the history of copper, there has been a lack of scientific attention on the part of producers of copper to the ultimate disposition of the metal. Today, however, I believe, not only producers of copper but the men who direct the rolling-mills in which copper and its alloys are shaped for the consuming market are beginning to manifest an interest in the final resting-places of their products.

The research that I have mentioned had to do in the main with the consuming end of copper. We have known all about the copper production and methods of refining and selling from the outset, these being matters of record. We have also known all about the methods of the rolling-mills, or 'fabricators' as they are called, and the proportions of copper, brass, and other alloys they produced in the standard finished materials such as wire, sheets, rods, and tubes, because these things, too, were matters of record; but at this point we found that records ceased, that no man or group of men had more than a vague idea of the proportionate consumption by industries.

Copper is no different from any other commercial product in that the amount you can profitably produce depends entirely on the amount the public will consume, yet we were unable to find that at any period in copper history any serious effort had ever been made by either producer or fabricator to study the consumer; or, what is more important, to educate him to the great superiority of copper and copper products over other commercial metals. And so copper and its alloys have gone on the market with the handicap of an initial cost higher than the metals in competition with them and without any concerted effort to justify this cost by informing the consumer of the great advantage and ultimate saving accomplished by their use.

It is a great tribute to copper and copper products that up to the time of the War they were able to more than hold their own in such circumstances. What has happened since then is well known. With Europe practically shut out of the American copper market through lack of funds, our copper industry has been obliged to turn to domestic consumption for existence.

And what has it found? It has found the market glutted with substitutes for which a tremendous demand has been created as a result of advertising, clever publicity, and intensive promotion efforts. It has found a public thoroughly well educated in what merit these substitutes possess, and keenly disposed toward them be-

cause they answer immediate requirements and are obtainable at a much lower cost than copper and copper products. They find that the public, generally speaking, knows little about copper, although it is the oldest of commercial metals. Of what use is it to have a superior article if the public doesn't know it is superior, and that in all its standard uses it works a large saving because of its everlasting life and absence of upkeep expense, to say nothing of its salvage value.

And so I feel that I can say that the present plight of copper is due in a large measure to certain neglects of the past. A substantial part of the losses in export business might be made up by an increased domestic consumption if the public knew the merits of copper and its alloys. Naturally, I am a strong believer in public education; I have seen too many instances of its success in business to have any doubt of its efficacy where it is employed in the interest of a product that has merit.

Twelve years ago aluminum was a drug on the market. Among retailers of kitchen utensils it was known as "lemon metal". Aluminum was used for about a quarter of 1% of the utensils in use in the United States. Under improved processes of manufacture a good grade of aluminum was produced, but so evil was the metal's reputation with housewives that it could not be sold. So a campaign of education was planned and carried out. Today aluminum is used for more than 50% of the utensils in this country, and the demand for it is steadily increasing. Copper has been almost entirely driven out of American kitchens, being used in the manufacture of only 6% of the utensils in use.

Who ever heard of Armco iron until the American Rolling Mills Co. began to placard the country with its merits, to get its message into every manufacturing establishment and every home in the country. In 1914, when its publicity effort began, its output was 25,000 tons per year. Today the output is 200,000 tons per year, and this will be increased as soon as additional mills, now being built, are completed.

Then there is Monel metal, an alloy that contains about 28% of copper, from which I am told it gets much of its merit. In the first eight months of its campaign of public education the International Nickel Co. more than tripled its sales of Monel metal.

All these metals are sold in direct competition with copper and copper products. It would be idle to deny that they have made serious inroads into fields once dominated exclusively or almost entirely by copper and its alloys. I could go on indefinitely in telling you about the results of these campaigns of education, but you probably are already familiar with many of them, so I will just direct your attention to the fact that substantial results have followed those launched in the last few years by the New Jersey Zinc Co., the American Face

*Speech of Ivy L. Lee, adviser in publicity and public relations to various corporations and interests, including the Copper and Brass Research Committee, at the annual meeting of the New York Section of the American Institute of Mining and Metallurgical Engineers, held at the Machinery Club, New York, on February 2, 1921.

Brick Association, the California Fruit Growers' Exchange, the California Raisin Association, and the Brazilian coffee-growers.

In our investigation we were unable to find any other industry that had allowed the product on which it depended for existence to run along by itself. There has been no scientific effort made to stimulate a demand for the metal and its alloys among natural consumers, to create new markets, or to protect the metals industries in which they had become entrenched by their sheer worth.

Years that have been marked by large increases in copper consumption have always been years in which the demand was created by some influence entirely outside the industry itself. In 1895, the middle of a notable decade in copper history, the production of copper in this country was only 380,000,000 pounds. Then came the sudden expansion of the electrical industry, the establishment of the long-distance telephone, and the extension of electric-railway systems in all parts of the country. This was followed by many new industrial enterprises, the automobile industry being a conspicuous example.

Then came wars, the Spanish-American, the Boer, the Russo-Japanese, and the Balkan wars, with their heavy demands for copper and copper products. Between 1895 and 1916, copper production jumped from 380,000,000 to 1,928,000,000 lb., and in 1918, under pressure of the demands of the world war, the production from domestic ores alone was more than 2,500,000,000 pounds.

Of course, you gentlemen know that such expansion would not have been possible on the basis of demand alone. It was made possible by the advance in mining methods for which some of you here are probably in part responsible, permitting the profitable working of low-grade ores, and by the discovery of new copper deposits.

I will not go over the wide range in prices of copper during the 25-year period that I have mentioned. As you know, copper prices always go up with increased demand! It is enough to say that after passing through various vicissitudes, copper got under way nicely at the beginning of 1920, at about 19c. and wound up the year with plenty obtainable between 12½ and 13c., but with practically no inquiries being made.

With the expansion of electrical enterprises in this country and the rehabilitation of European finance, the demand for copper and copper products should automatically reassert itself. To leave a great industry dependent on such spasmodic needs, and constantly facing the menace of such experiences as copper has gone through in the last year, however, is poor business. It seems to me to be a particularly ill-advised course when competing metals and materials, under the pressure of intensive promotion efforts, are steadily forging ahead in fields once almost entirely dominated by copper and its alloys.

Then how is the copper industry to be stabilized, to protect itself from these constantly recurring dangers of over-production? This question brings me squarely

up to the ultimate consumer, and by the ultimate consumer I mean everybody who uses pins, hardware, screws, nails; the man who owns a home or is about to build one and has the problems of roofing and plumbing to consider; the men who are engaged in the erection of office-buildings, apartment-houses, or hotels, and who in addition to their roofing and plumbing, have thousands of articles of ornamentation such as door-knobs, hinges, locks, bolts, window-catches, electrical apparatus and fixtures, and a myriad of other things to consider; the man who is going to buy an automobile and will never know unless he is told that vital parts formerly made of copper, because of its non-rusting qualities, are now made of steel.

I could make this list almost any length, for it is a fact that copper, brass, bronze, and other copper alloys, go into many hundreds of small articles that are in use in every American home. The enormous total tonnage represented by these things may be gauged from the fact that nearly 2,000,000 lb. of brass go into the manufacture of pins alone each year in this country.

Pins, by the way, are the only form in which copper goes into consumption, that represents no return in scrap. No human being has ever yet been able to find out what becomes of the pins.

To create a steady demand for copper and copper products, I believe it is necessary to work from the ultimate consumer up. You will rarely find a man who knows the qualities possessed by these metals using anything else, where resistance to corrosion, long life, and good service are required. When you have created an ultimate consumer demand, you have created a demand on the manufacturer of metal products, who soon hears of what the people want through the retailers with whom he comes in direct contact. The manufacturer is never slow to meet a demand, and his needs reflect themselves in increased orders for the products of the rolling-mills, to meet which the fabricator must buy more and more copper from the producer.

I will not dwell upon copper for electrical purposes. Copper for export depends on financial conditions and needs abroad, and cannot be controlled to any great extent by domestic promotion efforts. But the domestic consumption of copper—the output of which from our rolling-mills in finished materials in 1919 was 700,000,000 lb. without including wire—can be greatly increased and stabilized by public education.

While such a war as that just ended creates a tremendous demand for copper, it must be remembered that while it lasts it takes the metal entirely out of ordinary commerce. So when a war is over copper has got to work its way back into general use and it always finds a host of rivals that have flourished in its absence, ready to give it battle.

During the World War all the copper that could be produced was taken for munitions. When the War ended our Government had an enormous supply of the metal on hand, and the mines were still turning out at an extravagant cost of production, justified by the

emergency and by the protection afforded by the 26-cent rate fixed by the Government. So with the end of the War copper had to face a serious over-production, taken out of the mines at extravagant cost and no longer protected by the Government price. It also had the handicap of having been out of commerce for several years, during which time its rivals had securely entrenched themselves.

The job that copper had on its hands when the War ended was to get itself back into industry as quickly as possible. And here is where early neglects came home to roost. Those who had been compelled to sell substitutes during the war period made much larger profits out of these substitutes than they ever made out of copper or brass. Therefore they had no particular enthusiasm about promoting the interests of these metals.

Architects, builders, and plumbers, idle during the war period and hungry for work, refused to discourage prospective clients by specifying copper or brass for roofing, plumbing, or ornamentation, because to do so meant to increase the amount of a building budget.

Manufacturers of screws, screw parts, nails, and hardware generally, did very well with steel, thinly coated with copper or brass during the War; and as long as the customer made no complaint they did not think it necessary to return to real copper and brass afterward. And so it went all along the line, a situation tremendously aided by the advertising and educational work of the makers of these substitutes, who, scenting the menace in the return of copper and brass to commerce, redoubled their efforts to keep all that they had gained during the War. And in the main they have succeeded in keeping most of what they picked up while copper and brass were doing duty at the front.

When we started to find out what was the matter with copper and brass we made out a list of all consuming industries and all trades and professions that had either a direct or indirect influence on the consumption of these metals. Then we made first-hand studies of these industries, which included personal talks with the leading men in them. I would like to repeat to you some of the things these men told us. I will start with architects, and the architects are important because with their specifying powers they practically control the materials that go into building. Among architects there is almost complete unanimity concerning copper and brass. They do not regard any other metals used in the building as comparable to them, and they prefer to specify them as a matter of professional pride because they are the best, and naturally reflect credit on the architect when they are used. But architects were hard hit during the War, when building was at a standstill, and they needed all the work they could get. They told us that almost every client that came to them insisted on keeping his building budget within certain definite figures. There was no cutting the cost of standard building-materials, which was high right after the War, and there was no cutting the cost of labor. What they could do, and did do, was to eliminate from their specifications all materials having

a high initial cost and for which cheaper substitutes could be used. Of course, copper and brass came under this head, and they were ruthlessly sacrificed. Our architect friends told us they never had any trouble in doing this, as not one out of a hundred clients knew anything about copper or copper products.

Builders, plumbers, and roofers told us the same thing; many of them frankly admitting that they had gone so far as to argue clients out of the use of copper and brass, in order to keep a building budget down to a point where the client would be encouraged to proceed with his enterprise. In most cases, however, they said that the substitution of other metals for copper and brass went unquestioned.

Automobile manufacturers told us that they had cut copper and brass down to the lowest possible point during the War, because of the scarcity of these metals, and that they had continued the use of steel and certain patented alloys after copper and brass again became plentiful, because they found it cut down the cost of production and did not bring any complaint from the customers. At the same time they admitted that the tremendous growth of the automobile-repair business in this country during the past five years was due in no small way to the substitution of other metals for copper and brass in the working and structural parts of automobiles.

I have already mentioned the hardware industry, but there is one phase of this industry to which I want to call particular attention. Ninety per cent of those who today are buying copper- or brass-coated steel nails or screws believe that they are buying articles of solid copper and brass. When these articles fail to give satisfaction the fault is attributed to some shortcoming in the metal, and both copper and brass suffer in reputation.

I have already mentioned the losses of copper in the utensil field. Here is the situation on utensils as given to me by the leading dealers in kitchen-ware. Fifty per cent of all the kitchen utensils sold in the United States today are made of aluminum; 25% are of enamel-ware of different makes. The remaining 25% is divided among copper, iron, glass (Pyrex), and Monel metal, copper representing 6% of the whole.

Yet copper is admittedly the best metal for utensils, in spite of certain handicaps. Chief of these are the cleaning and the necessity of tinning. The cleaning problem should be overcome if any particular study ever had been made of it. But in present circumstances the tinning is an expensive operation and there are few places where it is done. In Europe the dealer in copper utensils takes care of these things. They have scores of different kinds of powders and pastes specially made for cleaning copper, and even in the smallest villages there are tanners who make a specialty of tinning the inside of the copper vessels used in cooking.

Among large manufacturers of foodstuffs, and in hotel and steamship kitchens, copper is still used to a considerable extent, but if you have watched the magazine advertising during the past year you will see that both the aluminum and Monel metal interests are making

a drive for this field and have developed special grades of metal to meet its requirements.

I need hardly tell you gentlemen of the superiority of brass over any other metal for piping, especially for hot-water supply. Yet in the large office-buildings, hotels, and apartment-houses in this city brass represents but a small percentage of the total outlay for plumbing. For instance, the plumbing in the Woolworth building cost \$450,000, of which only \$32,400 represents brass pipe. In the Western Union building the plumbing cost \$260,000, of which only \$19,500 went for brass pipe. The plumbing in the Commodore hotel cost \$900,000, of which \$3150 was spent for brass pipe. In the Pennsylvania hotel, the total cost of plumbing was \$1,450,000, of which \$36,000 represents brass pipe.

When I tell you that one of the largest manufacturers of brass piping in the country, a man who spends thousands of dollars annually inducing plumbers to encourage the use of his product, recently built a home for himself and installed iron piping, and that one of the largest fabricators of brass in the country has his entire plant equipped with glass door-knobs and glass hand-rails, you will understand how loosely the interests of the metal are cared for by the very men who produce it.

In the course of our studies we ran across many interesting things. We found that complaints were coming from all over the country that shingle roofs began leaking after being installed a comparatively short time. It did not require much investigation to explain this. The roofs had been laid with steel nails. As soon as the brass coating wore off, the nails began to rust, eating holes in the wood.

We learned that large manufacturers of women's garments and dressmakers generally were complaining that much material draped on forms had been ruined by the rusting of the pins used to hold it together. The explanation was simple. Steel pins, tinned, had been substituted for the brass pin, tinned, which was standard before the War. These are still being sold and will, I have no doubt, continue to be sold until a better understanding sends the dressmaker into a store with a demand for brass pins and a refusal to take anything else.

Merely to illustrate the losses that copper and copper products have suffered as a result of the War, I will mention two incidents. A large manufacturing concern in Ohio uses a 50-lb. metal box in which to encase a machine that it makes. Before the War this box always was made of brass. During the War, when brass was hard to obtain, steel was substituted. Steel is still being used. As the company turns out something like 400 of the machines a day, the annual loss to brass by this substitution is around 6,000,000 pounds.

The National Acme Manufacturing Co., of Cleveland, Ohio, manufactures screws and screw parts. Before the War it regularly cut 10,000,000 lb. of brass per year. During 1919 its consumption of brass was less than 3,000,000 pounds.

And so we find it through all the industries, galvanized iron, steel, zinc, and plastic materials substituted for

copper in roofing, iron substituted for brass in plumbing, and steel for both copper and brass in automobiles.

Once in a while these short-sighted economists come. a cropper. About a year ago a large manufacturer of electric batteries in the Middle-West decided to substitute brass-coated steel knurls for solid brass knurls on his batteries. He equipped 500,000 batteries in this way and figured he had worked a fine saving for himself, as every test he made indicated that the steel knurls gave perfect service. But in shipment the acid in the batteries came in contact with the knurls, utterly ruining them. He was obliged to call back shipments of these batteries from all over the country, remove the steel knurls, and put on brass ones before he could safely market them. This manufacturer told an associate of mine that the experiment had cost him thousands of dollars and would have seriously injured his business if the batteries had ever been put on the market. He will never use a substitute for brass again.

It is not my purpose in this paper to detract from the merits of the many metals and materials that have taken the place of copper and copper products; on the contrary, all of them have their uses. But there are fields in which copper is incomparable because of its resistance to corrosion, its easy handling of contraction and expansion, its uniformly excellent service, its everlasting life, and its salvage value.

In these fields, it seems to me, it should not be allowed to suffer, and I do not believe it would suffer if there was a better understanding of its real merits and the merits of the various alloys of which it is the principal content. A few months ago one of the largest roofers in this country told me that the cost of copper roofing, labor and material, was 45 cents per square foot, and the cost of galvanized iron, labor and material, 25 cents per square foot. Architects, builders, and roofers, he said, were inducing thousands of people to use the galvanized iron because it represented an initial saving of 20 cents per square foot. At the end of twenty years, however, this roofer estimated that with replacements and upkeep the galvanized iron would cost \$1.90 per square foot, with another entirely new roof about due, while the copper roof still would represent the 45c. investment, be perfectly good for another twenty to forty years of service and have a salvage value pretty close to what the material originally cost.

A large contracting plumber gave me a similar story about brass piping, and of some fifty prominent architects who were canvassed not one dissented from these estimates, or expressed any other view than that copper and brass were in a class by themselves for general building purposes and when used represented a very substantial economy in the long run.

Wherever copper or copper products are understood, they are used. In Germany whole store-fronts are of sheet-copper. In Turkey and certain other countries man's wealth is measured by the number of copper kettles he owns. In this country the virtues of copper and its alloys are not generally understood.

The Theory of Flotation

By Reginald S. Dean

INTRODUCTION. Flotation theory seems to be developing largely along the lines of study offered by the thermodynamical treatment of surface-tension phenomena. It cannot be denied that in the laws of thermo-dynamics we possess tools of the greatest importance and by this means many of the facts of flotation have reached a more or less lucid explanation. The recent paper of Sulman¹ has pointed out the conclusions that can be arrived at by thermo-dynamic means. In the present paper, however, I shall attempt if possible to get a definite physical conception of the various processes involved in flotation at the expense, perhaps, of the security one feels when treading the safer path of thermo-dynamics.

FORMATION OF A FROTH. Fortunately we have an exact physical conception of what happens when a frothing-agent is placed on a water surface, or, as the case may be, dissolved in water. For this conception we are indebted to Langmuir² and Harkins.³ For the purpose of illustration let us consider the action of oleic acid at an air-water interface. Oleic acid has the formula $C_{17}H_{33}COOH$, it belongs to the type of substances that Harkins refers to as polar, that is, one end of the molecule differs markedly in properties from the other end. Now

Fig. 1

when one of these oleic-acid molecules, in which *o* (see Fig. 1) is the polar group, in this case carboxyl, comes in contact with water the carboxyl group being soluble in water⁴ turns toward the water and the molecule is oriented as shown in Fig. 1. All the oleic-acid molecules will behave alike, so that if there is not too much oleic acid it will spread out to a layer one molecule thick. Similarly if the substance is soluble in water the surface layer will

Fig. 2

have oriented molecules if they possess a polar group, or, in other words, polar substances are adsorbed at the air-water interface. Thus with phenol, C_6H_5OH , we have an orientation as in Fig. 2, the hydroxyl group being the soluble portion.

If a substance possesses no polar group, it will not spread at an air-water interface, thus paraffin oils do not spread. We are therefore in a position to infer with reasonable certainty from its chemical formula whether a substance will spread on water to a layer one molecule thick or not.

From this to the formation of froth is a simple step. If there is sufficient polar substance present it will spread on all the available air-water interface. By introducing bubbles the air-water interface is increased, so it is to be expected that the substance will spread at the surface of the bubbles; this gives a froth. A froth is an aggregation of bubbles with a polar substance spread over their surface. The function of the polar substance is, clearly, to stabilize the aggregation. The stability of the froth depends on the nature of the adsorbed substance. The separation of flotation agents into frothing and non-frothing is an artificial one. All substances that are effective in flotation when used alone must possess frothing properties, as will be clear later. The kind of froth produced by the two types of flotation agent is different, but all flotation agents must be capable of adsorption at bubble surfaces. The question of the action of a mixture of polar and non-polar substances could readily be determined experimentally and would answer the once interesting question as to whether, in a mixture of paraffin and pine-oil, the paraffin is a part of a functioning mixture.

INCLUSION OF THE ORE-MINERAL IN THE FROTH. It has been pointed out by C. T. Durrell⁵ that adsorption or solution of a gas by a mineral is a necessary condition to the flotation of the mineral. This has perhaps not been conclusively proven, but there are a number of facts which point to its correctness. The amount of various gases adsorbed by the sulphide minerals is especially large. The only quantitative data with which I am familiar on this subject were obtained by H. Bajoulian under my direction at the University of Pittsburgh some years ago. The following table gives the number of cubic centimetres of gas absorbed by 1 cc. of 80-mesh mineral.

Gas	Mineral			
	Galena	Sphalerite	Chalcocite	Copper
Air	0.018
H ₂ S	0.889	0.814	0.624	0.599
H ₂	0.234	0.036	0.108
CH ₄	0.122
SO ₂	1.139	1.082	4.254

⁴I assume the solubility of the carboxyl group. As the hydrocarbon chain is shortened the acids become more soluble, finally, as with acetic acid, CH_3COOH , and formic acid, $HCOOH$, there is complete miscibility.

We see that the amount of such unsaturated gases as hydrogen sulphide and sulphur di-oxide absorbed is particularly large, and even air is absorbed appreciably by galena. The amount of these gases absorbed by silica is practically nil, and calcite absorbs only the acid gases. Whether these gases are adsorbed or dissolved is of no importance just here. We do seem justified, however, in assuming that a sulphide mineral will have a gaseous envelope under normal circumstances. From the amount of absorption we would infer that the gas is held rather tightly, and this is true of metallic surfaces in general as compared with such substances as mica. Water will not therefore displace the gas. Any mineral that absorbs gas strongly is nothing more than a weighted bubble when placed in water; in the flotation process it becomes a part of the froth, the buoyancy of which is sufficiently great to lift the mineral.

EFFECT OF ADDITION AGENTS. This theory of flotation leads to a simple chemical explanation of the effect of many addition agents. The value of acid in zinc flotation is doubtless due to the evolution of hydrogen sulphide from the sphalerite to give a gaseous envelope. In a previous article⁶ I have explained the action of the Bradford process on this basis. The accelerating action of copper sulphate in floating some sphalerite is probably due to its increasing the ease of solution of the sulphide, just as copper sulphate increases the rate of solution of zinc in acid. In the latter case, copper is deposited; in the former, copper sulphide. In the extended work of Mann and Thornberry⁷ on the use of addition agents in the flotation of a lead ore in a limestone gangue they found that only cadmium, uranium, and stannous salts were particularly deleterious. This may be explained by the precipitation on the surface of the galena of the sulphides of these metals; this would certainly take place with cadmium and tin; uranium is doubtful. Many other addition agents were tried that will give precipitates with lead sulphide, but most of them, as with silver and mercury, would probably absorb gas or might be thrown out of solution by the limestone. A knowledge of the gases absorbed by actual minerals would certainly throw some light on the action of addition agents toward them.

Another type of addition agent is one that affects the polar character of the flotation agent. Thus sodium hydroxide, added to the pulp when coal-tar is being used, forms salts with the phenols and cresols present, which are more soluble and hence more polar than the phenols. A number of similar instances might be mentioned. Some addition agents might destroy the polarity of the flotation agent altogether; this is the case with the addition of acids to some amines. It is evident that the chemical properties of a flotation agent may be as important as the physical properties and they are much more easily predicted.

In the foregoing only the simplest cases have been treated, and important relations between the nature of

the mineral and gas adsorbed have not been discussed, but I believe the theory as outlined constitutes a usable working hypothesis. In conclusion, I may summarize the conditions necessary for flotation according to this theory:

1. A gaseous envelope around the mineral to be floated.
2. A polar substance as a flotation agent.
3. The absence of addition agents that will react chemically with the gaseous envelope or the surface of the mineral or affect the polarity of the flotation agent adversely.

Mint for China

The first step in an effort toward uniformity in Chinese currency will be undertaken by the building in Shanghai of China's first national mint. The work will be directed by an American expert, Clifford Hewitt, of Philadelphia, whose services have been loaned to China by the United States. Mr. Hewitt installed the new mint at Manila, the first established in the Philippines. It is expected the completion of the Chinese mint will put an end to the conglomerate system of currency of all kinds and values which has long been a drag on the commercial progress of China. Although the Mexican dollar, introduced into China from the Philippines, has come to be the common unit of value, the various tuchuns, governors, and other officials of provinces have issued coins that are dealt with commercially at values based on the quantity of their silver content. The Chinese tael in which government funds and customs ordinarily are reckoned is not a coin at all, but a silver slug of a given weight and fineness, differing in weight and value in the different provinces. The Shanghai mint is to cost about \$2,000,000 and will be one of the largest in the world, rivaling in size and output the mint at Philadelphia. It is to have a capacity of 500,000 silver dollars per day with a daily consumption of 14 tons of silver in addition to baser metals used as alloys. Mr. Hewitt hopes to have the plant in operation within two years. He is the originator of many of the machines and processes in use in American mints, having been in the service of the United States government 24 years. He built the American mints at Denver and Philadelphia.

THE COLOMBIAN CONGRESS on November 20, 1920, passed a law permitting the free exportation of gold in all its forms except money, upon proof that such gold is not the result of the melting down of gold coins, states a consular report. It is apparently the general belief here that this permission, together with the decrease in imports incident to the high rate of exchange, will, for a time at least, effect a gradual lowering of this rate. The active exportation of gold, which has been carried on for some months past by speculators on the coast, has been closely correlated with the fact that the rate of exchange has averaged considerably lower on the coast than in the interior. This, of course, has had the effect of drawing gold from the interior for the purchase of drafts on the United States.

The Sampling and Estimation of Quicksilver Ore

By C. N. Schuette

Much has been written on the theory and practice of mine-sampling,* but with one exception† I have failed to notice any discussion of the sampling of quicksilver ore. The following remarks on factors affecting the sampling of such an ore may be of interest.

Quicksilver ore occurs in a variety of gangue materials the most common being sandstone, limestone, serpentine, andesite, rhyolite, basalt, and chert. Two general types of deposits are found. These are low-grade (two to five

Fig. 2 is a section of the Oceanic mine, in San Luis Obispo county, California. Here the 'mud-rock', a gray fine-grained sandstone, formed the impervious stratum and the mineralizing solutions deposited the cinnabar in the underlying coarser sandstone. This particular impervious bed was only relatively impervious; and the 'mud-rock' constitutes a low-grade orebody, so that in this mine neither wall is well defined.

Fig. 3 shows a section through the Cloverdale mine in Sonoma county, California, in which the cinnabar is deposited in extensively fractured flat strata of radiolarian chert. This chert is capped by an impervious gouge and the ore becomes poorer from this gouge outward.

Fig. 4 gives a section through the

Fig. 1

pounds of mercury per ton) evenly disseminated ores, and ores of irregular deposition.

A clear conception of the geology is of the utmost importance in the examination of a quicksilver deposit. In the formation of most deposits of this ore, two factors appear to have been dominant: first a relatively impervious stratum directing or limiting the upward flow of the mineralizing solutions, and, second, the porosity of the rock underlying this impervious cap. The generalized cross-sections of several mines, shown in Fig. 1, 2, 3, and 4, illustrate the influence of these two factors.

Fig. 1 is a section of Mine Hill at New Almaden, in Santa Clara county, California, after Forstner.‡ The 'alta' here forms the impervious stratum and the distribution of the ore depended on the inclination of the 'alta' and upon the intensity of fracturing in the vein-material.*

Fig. 2

Mariscal mine in Brewster county, Texas. Here the mineralizing solutions ascended in a fissure in the limestone and were arrested in their upward course by a sheet of intrusive rock.

Mr. Forstner's bulletin, cited above, gives numerous sections showing similar relationships.

At the St. John's mine, in Solano county, California, the ore occurs in dike-rocks brecciated by faulting.§ The soft shale surrounding the dike-rocks formed gouges, but did not brecciate on faulting; hence no open spaces were formed in the shale for the circulation of the mineralizing solutions.

In several mines the richest ore is found filling the interstitial spaces in coarse breccia, as at the Chisos mine in Texas and at the Goldbanks mine in Nevada.

Associated minerals are significant. Thus pyrite may be an indication of the nearness of cinnabar. In a few mines a pyrite stringer may lead to cinnabar within a

‡Bulletin 27, California State Mining Bureau, 'Quicksilver Resources of California', by William Forstner.

*The Spanish term 'alta' refers to a dark gouge or clay on the hanging wall of quicksilver lodes in California, particularly at New Almaden. The word 'caliche' is used for the same purpose at the New Idria mines.—Editor.

distance of about 30 ft. In one mine were found two types of calcite vein-filling; one formed thin coatings of fine crystals and was associated with the ore, while the other formed large crystals and masses nearly filling the barren veins.

The cost of development work in quicksilver mining is high on account of the irregularity of the orebodies. Development work if possible is done in ore. The cost of driving raises and drifts is higher than the cost of stoping, so that the tendency is to run drifts and connections in the best ore rather than at regular intervals.

The hanging-wall limit of the ore is generally sharply defined, whereas the foot-wall side is less definite. The assay-value of the ore may change rapidly and without warning, so that a good deal of waste is unavoidably broken on the foot-wall side of the deposit, this barren rock being sorted out at surface. The breaking of this waste makes the stoping-width appear larger than it actually is. Cinnabar ore, because of its bright red color, is easily sorted, as much as half the ore mined being picked out as waste at some mines.

Operators have been criticized for lack of sampling and assaying at their mines. When the outbreak of the War stimulated the industry to unwonted activity, several engineers having no previous experience with quicksilver began at once to 'modernize' the industry. One step in this process was extensive sampling and assaying, with ludicrous results, as this ore cannot be sampled in the manner usual with other ores. Cinnabar is so very brittle that groove-samples are untrustworthy except in low-grade and evenly disseminated deposits. This very brittleness of cinnabar, however, makes it amenable to accurate estimation by panning. Thorough rubbing of the ore between the hands liberates the cinnabar from the gangue, and the larger pieces of gangue, after inspection, can be discarded.

This method of estimating the content of an ore is rapid and with practice a surprising degree of accuracy is attained. Certainly the accuracy of estimation is well within the sampling-error. This statement may seem an exaggeration to many, but panning, when done by experienced men, is recognized as a legitimate method of estimating ore in the quicksilver industry the world over. Oschatz states[¶] that most of the miners at Monte Amiata, in Italy, are proficient in panning. He cites one who could invariably check assays within a limit of error of 0.1% mercury. That is exceptionally good work on the high-grade ore of those mines, but on low-grade ore and with careful panning even closer results are obtained. The error of a number of samples is compensating rather than cumulative.

The development work of quicksilver mines is not generally carried far enough ahead of mining operations. For this reason and because of the irregularity of the orebodies, both in shape and value, it is necessary to sample the various working-faces after each blast, in order that the requisite tonnage of a certain average grade can be

delivered to the reduction plant. This sampling is done by inspection or by panning. The former is a fair method of judging ore, as cinnabar is readily visible on a clean face. For the latter method, an old carbide-can or pail full of water and a small six-inch pan are kept near each face.

With practice the foreman and miners become expert in predicting the change to be expected by the next blast, so that dressing a quicksilver mine for examination can be carried to the point of fine art.

All quicksilver mines have their own reduction plants, so that the engineer, knowing the amount of waste sorted, can check his daily pannings against actual production, and thereby becomes proficient in estimating the quality of the ore.

To sample a quicksilver mine, the examining engineer should be familiar with quicksilver ore and the mining of it. The first requisite for an examination is a map of the mine. With this map and a prospector's pick, a visual examination should first be made to determine the geologic relationships of the orebodies and the general trend and limits of the mineralized zone. Following this preliminary examination the mine should be blocked into the smallest units permitted by the mine-openings. A visual determination of the grade of ore in each block should then be made, the value being estimated at fixed intervals along the cleaned faces, and plotted on the map. This visual examination is followed by panning samples at fixed intervals along the faces, the samples to be cut with a prospector's pick in the same manner that the daily samples are usually taken. The results of these two estimates should then be compared and any unreasonable discrepancies should be adjusted after re-estimating the section in question.

In the calculation of tonnage, particular attention must be paid to the density of the ore, as this may vary as much as 20% in the same mine. This difference in unit-weight is found between high and low grade ore, owing to the difference in cinnabar content, or it may be due to a difference in the pyrite content of the ore, outcrop ores generally being devoid of pyrite.

In determining the future possibilities of the mine, it is important to have a clear conception of the general trend of the mineralized zone. Generally speaking, all the separate orebodies can be encompassed in an imaginary lens, as suggested in Fig. 5, the lower axial extension of which points in the direction of possible orebodies. This has less bearing on the possible existence of other orebodies than the geologic data, but it aids in determining the probable cost of mining such possible orebodies.

The sampling method outlined above is possible because cinnabar is readily visible to the eye on clean faces, and, owing to its brittleness, is amenable to accurate estimation by panning. This method of sampling a quicksilver mine, when carried out by an experienced engineer, will give the content of the orebodies as accurately as the content of more regular orebodies of other metals can be determined by standard sampling practice.

[¶]K. Oschatz, 'Die Verhüttung der Zinnerzerze am Monte Amiata, in 'Glückauf,' September 28, 1918, p. 609.

The price of quicksilver is so unstable, in addition to the irregularity of the orebodies, that a quicksilver mine, to be attractive to capital as a venture, must promise a larger margin of expected profit than other mines. This gives a larger factor of safety for the actual capital invested in a quicksilver mine, provided only that the

FIG. 3

investment was based on the report of a competent engineer.

Spassky Copper Mine

At a recent meeting of the Spassky Copper directors the chairman said:

"We have again been cut off from our properties for twelve months, but I am glad to be able to give you some news of as late a date as August last. A gentleman who has recently returned from Western Siberia has been good enough to give us some highly interesting information. It appears that no

FIG. 5

damage has been done to the Spassky properties, and that the colliery at Karagandy is being worked on a small scale to supply local demands for coal. The smelter was not then being run, although it was reported that they intended to start it to work on some concentrates. The Yuspenssky mine is unwatered, and the pumps are being kept going. At Atbasar no work was being done, but a young Russian engineer was in charge as caretaker. Food supplies are said to be very short, and clothing practically unobtainable. The transport question is more difficult than ever owing to the shortage of horses, oats, repairs to carts, etc., and in con-

sequence there is a serious timber shortage. Beyond small thefts of movables by looting marauders you will hear with satisfaction that no serious damage has been done at any of our properties. Having regard to the actual position in Russia this is, I think, about the most satisfactory news that we could have received, because I need hardly point out that anything like organized destruction might have resulted in serious and almost irreparable damage. Our properties, as most of you know, consist of two main groups, the Spassky and the Atbasar. The Spassky group includes the Yuspenssky mine, where we have some 400,000 tons of proved ore estimated to contain 30,000 tons of copper, and the Karagandy coal

FIG. 4

mines, estimated to contain 400 million tons of good coal. There are also large smelters and works at Spassky, with our own railway connecting it with Karagandy, and then there is a concentrating plant at Sari Su.

"In the Atbasar groups we have huge copper deposits, of which we have only worked over a very small portion, but we have already proved upward of a million tons of ore, estimated to contain approximately 100,000 tons of metallic copper. In this group, also, we have coal deposits at Bai Kanour, although of an inferior quality to those at Karagandy, and a large smelter

which is partly completed. It would have been finished long ere this had it not been for the War and the subsequent revolution, and you would have been receiving substantial results for the money you have invested in that part of our undertaking. This very brief summary will show you that the possibilities of damage were large, but as we have avoided it so far it is not unreasonable to hope that we shall continue to do so, and particularly because we have a good record throughout the Steppes, and have done a great deal to raise wages and the whole standard of living among both Russians and Khirgees."

Income-Tax Returns

For the calendar year 1918, 4,425,114 individuals filed returns in the United States reporting aggregate net income of \$16,000,000,000, income-tax on which was \$1,127,721,835. These figures register a growth above 1917 of nearly 1,000,000 returns and approximately \$2,273,000,000 net income, as well as an increase of approximately \$437,000,000 in tax paid.

Of personal returns filed, 1% representing 43,000 people with incomes in excess of \$25,000 reported 17% of total personal net income and paid 66% of personal tax, whereas 99% of returns representing incomes under \$25,000 reported 83% of net income and paid 34% of the tax.

Of this great aggregate income, salaries and wages produced nearly half, or \$8,300,000,000 and business is credited with slightly over 25% or \$4,600,000,000. These two sources, representing incomes from personal endeavor, contributed nearly three-fourths of income reported. Of 958,000 people who reported incomes from business pursuits, 39% were engaged in agriculture, and reported net income of \$1,123,000,000.

Comparing 1918 with 1917, there was a slight decrease in returns filed by individuals having incomes between \$1000 and \$2000; there was a very large increase in those reporting incomes up to \$25,000, from which point on through the higher income classes a steady decrease is recorded. In 1918, 6457 fewer persons reported incomes in excess of \$25,000 than in 1917. The class reporting incomes of \$1,000,000 and over lost 74, the number between \$500,000 and \$1,000,000 decreased 137, between \$300,000 and \$500,000 the decrease was 177, between \$150,000 and \$300,000 it was 833, and between \$100,000 and \$150,000 it was 944.

Correlating the decrease in number reporting in higher income classes, between 1918 and 1917, with sources of income reported, those with net of \$100,000 and over show a decrease of 2165, and aggregate decrease in income of \$521,000,000, of which approximately 79% was due to decline in dividends; interest on investments decreased \$65,000,000 or 12%, and rents and royalties \$11,000,000 or 2%. Salaries, fees, and commissions showed a net reduction of \$40,000,000, whereas business, partnerships, and profits from incidental sales of securities and real estate increased \$4,000,000.

In income classes from \$20,000 upward, the falling off in dividends was \$559,000,000, whereas in classes between \$2000 and \$20,000 there was an increase from this source of \$133,000,000. Whereas interest on investments reported by persons having incomes in excess of \$20,000 fell off \$80,000,000, such income in class between \$2000 and \$20,000 increased \$406,000,000.

It would appear that the decline in dividends was more or less general and that although the lower classes up to \$20,000 showed an increase from this source, this was probably due to augmentation of 1,083,000 persons not previously reporting in these classes. However, it probably was to a certain extent due to acquisition of divi-

dend-paying securities formerly held by persons in higher income classes.

Corporations that filed returns in 1918 were approximately 318,000, exclusive of personal-service corporations, of which there were 3500. Of the above corporations 202,000 returned net incomes aggregating \$8,400,000,000, on which income tax was \$653,000,000 and war profits and excess profits tax \$2,506,000,000, making a total of \$3,159,000,000 or 38% of their net income. Number of corporation returns for 1918 was less than in 1917 by 33,000; and although net income reported was also below the amount returned in 1917 by \$2,370,000,000, the tax exceeded 1917 by \$1,017,000,000.

The decrease in net income was due in part to exemption of dividends from tax. Predominant in industrial groups of corporate industries, based on net income returned, was manufacture of metals and metal products, whose net income was over \$2,000,000,000 and represented 25% of aggregate income for all corporations.

Following this in order of importance are:

	% net of all corporations	Net income
Trade	13	\$1,055,000,000
Transport and other public utilities.....	9	778,000,000
Manufacturers of textiles and textile products	9	765,000,000
Finance, banking, and insurance.....	8	685,000,000
Mining and quarrying	6	568,000,000
Manufacture of food products, liquors, and tobacco	6	530,000,000
Manufacture of chemical and allied substance	5	395,000,000

Agriculture and related industries represent less than 1% of total net income reported by corporations.

Number of returns reporting lesser incomes follows:

Income class	Number of returns
\$500,000-\$1,000,000	1,171
250,000- 500,000	2,054
100,000- 250,000	5,383
50,000- 100,000	7,224
10,000- 50,000	37,053
5,000- 10,000	29,780
2,000- 5,000	49,397
Less than 2,000	68,973

The curious results of the operation of the profits tax, as evidenced by wide range in rate of tax paid by various industries, are of interest. The highest rate was paid by corporations whose business was classed as construction. Average rate of tax for this group was 54.10%, although within the group were several concerns whose tax averaged 67.76% of net income. The next highest was manufacture of textile and textile products, with average rate of 51.50%.

In the transportation and other public utilities group the rate of tax was 19.30%, and the finance, banking, and insurance group had the lowest tax rate of only 17.93%.

ROLLED GOLD, produced by the mechanical plating of base metals with a thin film of gold, was invented in Birmingham about 60 years ago, states a consular report. For a long time the exploiting of the invention was left largely to Americans and Germans. The fineness and thickness of the gold plating vary considerably. For links and chains the thickness of gold ranges from one-tenth to one-fortieth of an inch; for the cheapest kinds of imitation jewelry it runs as low as one-hundredth. For the majority of what are considered good rolled-gold articles, gold of 12- to 14-carat fineness is used.

The Licensing of Engineers

A bill has been introduced in the Montana Legislature that proposes to create a State Board of Engineering Examiners, for the purpose of licensing engineers. A committee of the Montana section of the A. I. M. & M. E. has prepared a report on the bill, which is given herewith.

SUMMARY OF THE LAW BY THE COMMITTEE. The bill affects all engineers and land-surveyors, including employees of other engineers and surveyors, and of corporations and individuals.

After one year from the passage of the Act, no person may engage in "professional engineering" without obtaining a certificate of registration (hereinafter called a 'license'). Professional engineering, as defined, corresponds generally to what is usually known as engineering work, except that it includes "the design and supervision of mining operations and of processes and apparatus for carrying out such operations". The execution of work as a contractor or as a subordinate under a professional engineer, or by an owner on his own property, is not deemed professional engineering.

License may be obtained, after examination, from a board of five engineers, to be appointed by the Governor. The board meets twice a year.

The character and scope of the examination is within the discretion of the board. The principal qualifications for examination are six years' practice of professional engineering or land surveying, or graduation from a recognized engineering school; and citizenship or 'first papers'.

The fee for examination is \$15. An additional \$10 must be paid for license, and license must be renewed annually, at a cost of \$5.

License to practice is not general, but extends only to specified branch or branches. A civil engineer may not practice as a mining engineer; a land-surveyor may not practice engineering unless specifically authorized.

Within one year of the passage of the Act, licenses may be issued without examination to engineers and surveyors who have practised ten years; graduation from an engineering school shall count as four years' practice.

Licenses may be issued to engineers from other States that have license laws similar to those of Montana, on payment of a fee of \$10. There is no provision for engineers from Canada or from foreign countries.

Violation of the law is punishable as a misdemeanor, with a maximum fine of \$500, or three months' imprisonment, or both. Government engineers and licensed architects are exempted from the provisions of the law.

AFFIRMATIVE ARGUMENTS. The bill was drawn up presumably by the Montana Assembly of the American Association of Engineers, at least they are now actively urging its consideration. In order that the merits of the bill could be fairly presented to those most interested, a

committee of the A. A. E. favoring the bill was asked to prepare arguments in its favor, and herein below is given the affirmative argument as set forth in the reply received from that committee.

"The constitutionality of such a law is based on its promoting public welfare by safeguarding life, health, and property. It will accomplish this by the elimination from practice of incompetent and ignorant men who pose as engineers, but who are not fitted by their training and experience to have responsible charge of engineering work. The State already regulates and accomplishes like purposes in the practice of medicine, dentistry, law, pharmacy, and architecture. The argument that the Engineers' License Law will not eliminate all incompetents is not a good argument against such a law, any more than it would be a good argument against licensing the medical or legal profession.

"The law will give engineers a legal standing. It will definitely decide just who are and who are not engineers. At the same time it will not prevent any bona fide engineer from either outside or inside the State from practising.

"The law will elevate the standard of engineering practice due to the elimination of incompetent and unscrupulous men. It will tend not only to eliminate the class of men who make blunders, but also those who are dishonest in the practice of their profession.

"The operation of the law will be self-sustaining, as provision is made that at no time shall the amount of warrants exceed the total amount of fees paid under the Act.

"If it were possible to tabulate figures showing the annual expense to taxpayers caused directly or indirectly by incompetent engineers the total would be a very large one, and when it is also considered that engineering blunders often cause loss of life it is time to give serious thought to a measure which will tend to eliminate the men most likely to perpetrate these blunders. Under our present system of no regulation, a man who is a carpenter today may pose as an engineer tomorrow, and may actually attempt engineering design or execution of work."

NEGATIVE ARGUMENT BY THE COMMITTEE. I. The bill is not well drawn.

(a) Construed literally, it requires that the superintendent of every little mine and prospect be an engineer. While, in the exercise of common sense, the courts would probably hold that the law was intended to apply to the enumerated occupations only where professional knowledge was required, yet a decision to that effect would open all occupations to judicial inquiry as to whether they involved professional skill; and it cannot now be said who would and who would not come under the provisions of the proposed law.

(b) Section 1 provides that no person other than a registered professional engineer shall practise professional engineering in Montana. But Section 8 (c) says the applicant before admission to examination for registration, must show that he has been engaged in the practice of professional engineering for at least six years. A violation of Section 1 is required by Section 8 (c), for applicants other than engineering school graduates. He cannot get this six years' experience as a subordinate or assistant because Section 3 (c) 2, says "The execution as a subordinate, of engineering work, under the direction of a professional engineer", is not deemed to be the practice of professional engineering. Under the law as proposed it will be impossible for any, except engineering school graduates, and those already qualified by experience, to acquire the necessary practical experience in Montana to qualify for examination.

(c) There is no provision for the expenses of the board for the first year, during which licenses are not required to be taken out, and during which it is to be presumed no fees will be paid in. Furthermore, we doubt if qualified prominent engineers can be found to serve on the board thereafter at \$10 per day.

II. The arguments of the proponents of the measure, presented in various forms, amount to this, and to this only, that it will eliminate incompetent and unscrupulous men.

(a) No reasons for such a conclusion are presented. The experience in other States having similar laws is not given; and we may say that from our investigations as to the operation of such laws, we are unable to prophesy any good results in Montana.

(b) We do not believe the law will eliminate the unscrupulous or the incompetent engineer because:

(1) The board of examiners will not inquire into the honesty or integrity of the applicant for license. This being true, the law will not only fail "to eliminate unscrupulous engineers" but it will put Montana's stamp of approval on any engineer smart enough to pass the examination, and it will give him a standing which he otherwise could not obtain.

(2) Lack of employment does now and will continue in the future to curb sufficiently the activities of the incompetent engineer. The proposed law presupposes inability on the part of the employer to correctly judge the competency of his employee.

(c) No one would object to legislation prohibiting the misuse of the word 'engineer'; but the facts are that the real damage is not caused by men whose activities would be ended by the proposed law. Neither mining companies, railroads, nor municipalities employ for technical work men who cannot pass State examinations; and private citizens do not casually employ engineers as they do doctors and dentists. The real injury to the public and to the engineering profession comes from men who are competent enough, so far as examinations would show. Their sins are not mistakes, but misrepresentations.

(d) It is true that the board is given power to revoke licenses for fraud or deceit; but this power is necessarily

subject to review by the courts, before whom, on appeal, the fraud or deceit must be legally proven, and is legally unprovable. On the other hand, it is safe to say that the "legal standing" to be given engineers would be effectively cited in all engineering reports which were intended to mislead the public.

III. The bill purports to be for the benefit of the public; and its proponents have convinced themselves that such is its purpose; but if this law is for the benefit of the public, by what right is its cost imposed on the engineers? How will it benefit the public to exclude eminent foreign engineers from Montana? We submit that the underlying purpose of the bill is the protection from competition of Montana engineers.

Whether or not engineers ought to have such protection, we need not now consider; but we think that for such purpose the proposed law would be ineffective, and to the engineers not worth its cost to them; but more especially we think that an attempt to secure protection through a law camouflaged as a law for the public good, would not be in keeping with the high ideals of the engineering profession.

IV. To sum up: the law is not needed; the public has not asked for it; it adds another board to the list of State boards, already too long; it creates a few more political jobs; it imposes a serious burden, in time and money, on the engineers.

Respectfully,

SAMUEL BARKER JR.,
J. L. BRUCE,
F. W. BACORN,
RENO H. SALES,
E. A. BARNARD,
Committee.

IN future years mining activities will probably form one of the principal sources of revenue of the territory comprising the Canton district of China, and the subject, according to a consular report, deserves emphasis because of the potentiality indicated through available information. Mineral resources of the region are of wide variety and richness, including coal, tin, antimony, copper, iron, limestone, wolframite, lead, molybdenum, zinc, quicksilver, gold, and silver. Causes which until now have tended to obstruct any large-scale development of these resources may be summed up as general backwardness of the people, unsatisfactory internal conditions, and lack of adequate transportation facilities in places. Furthermore, the wide fluctuation in value of silver, as compared with gold, at times automatically opens and shuts the door to foreign markets, discouraging attempts at steady production, and damaging organizations of trained workers built up by years of effort.

MUNTZ METAL is an alloy of 60% copper with 40% zinc, and is used in place of copper for amalgamating purposes. Its adoption has been said to result in certain advantages including less corrosion with cyanide solution than when the ordinary copper plate was used.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

SODIUM-SULPHATE PLANT WILL BE BUILT AT JEROME.

JEROME.—Plans for the erection of a 150-ton plant for the production of sodium sulphate, at an immense deposit near Camp Verde, have been announced by the Western Chemicals, Inc., of New York City and Tonopah, Nevada. Residents of the Verde valley first heard of the salt deposits at Camp Verde when a government expert warned them not to feed that particular kind of

	%
Sulphate of soda (Na_2SO_4)	99.76
Calcium oxide (CaO)	0.12
Magnesium oxide (MgO)	0.02
Chlorine (Cl)	0.10

The average price of 95% salt-cake, f.o.b. Clarkdale, is \$21 per ton, and the cost of laying down the finished material at that point has been estimated by Lindsay Duncan, San Francisco engineer for the Western Chemicals Co., at \$10 per ton.

TOP OF 25,000-TON ORE-BIN. RAY CON. MILL AT HAYDEN, ARIZONA

‘rock salt’ to their cattle. It now appears that the deposit is one of the most valuable of its kind that has ever been discovered.

The plant to be erected will produce 150 tons per day of neutral acid-free salt-cake, containing more than 99% sodium sulphate. The mining will be done by steam-shoveling and quarrying. Trams will convey the material to the crushing plant, and from there it will be conveyed to another part of the plant for the extraction of the insoluble material. The finished product will be ready for the market.

A government analysis of the sulphate follows:

TUCSON.—A strike of ore on the 300-ft. level of the El Tiro mine has been developed to show a total of about 7,600,000 tons in the ore-reserves, according to W. H. Buehlman, secretary and assistant manager for the El Tiro Leasing Co., which is now operating the mine. The development on the 300-ft. level came after driving for 1000 ft. through a barren zone. The ore has been cut for a distance of 40 ft. and opened by cross-cuts to 15 ft. in width, assaying 7.18% copper.

OATMAN.—A referendum among the miners to determine whether to go on strike or accept a cut in wages resulted in a vote favoring acceptance of a reduction of

pay under protest. Joseph Lord, Federal Mediator, conferred with the workers and operators. Two propositions were submitted. The first was: "Shall we accept the \$1 reduction proposed with a protest?" The second: "Shall we resist the proposed reduction by a strike?" There were 140 votes for the first proposition and 49 for the second. Ninety-five of the miners declined to vote.

COLORADO

CRIPPLE CREEK DISTRICT IS NOW ACTIVE.

BRECKENRIDGE.—Boyce Brothers, who last fall opened a quartz vein assaying from 2000 to 3000 oz. silver per ton, have a sacked shipment ready to be forwarded to the Leadville smelter as soon as the road is open for hauling by team.

Brooks-Snider lessees continue producing high-grade ore. A 14-ton shipment was sent to the A. V. smelter at Leadville last week from the Carl Williams lease, estimated to assay 100 oz. silver per ton. High-grade gold ore is being sacked on the Auge lease on the Brooks-Snider. Samples are classed as 'picture' rock and assay thousands of dollars per ton. The mills of the Wellington mines are still inactive, but underground development continues. Operations are to be continued on the properties of the Rilla Gold Mining Co., and the claims carried to patent.

CRIPPLE CREEK.—The Edna Forest M. & M. Co. is operating four machines in the cross-cut into Dante ground from the 12th level of the Gold Sovereign mine, and in developing veins exposed in the Dante shaft fourth and sixth levels. Offices have been established at Cripple Creek with Thomas W. Meers, secretary-treasurer, in charge. Many applications for leases are reported and many properties long idle are again active. The number of coaches on the work-train have been increased and are crowded with miners.

DENVER.—The State Industrial Commission has granted the request made by mining companies for a general reduction of 50c. daily without protest from miners in any of the camps affected. The men tacitly agreed to the reduction and mines are working full handed.

GEORGETOWN.—Operations are to be resumed on the Centennial and Tobin properties of the Palisade Copper Co. at East Argentine and preparatory work is now under way. The Centennial Level is to be extended to connect with the Tobin workings and an ore-zone in the Smith tunnel will be exploited. Rich silver-lead ore has been opened up on the Sunburst by George Teagarden and associates, assaying as high as 129 oz. silver and 25% lead.

IDAHO SPRINGS.—The Gem Mining Co. plans to remodel the Argo mill at an estimated cost of \$150,000. The original cost was \$200,000. An additional \$75,000 will be expended in mine development. The mill capacity will be increased to 200 tons per day. Milling and smelting-grade ores are being mined from the Argo tunnel on the Lost Mada vein, between the 1400 and 1600-ft. levels, the ore having high gold-silver-lead content.

MICHIGAN

ISLE ROYALE HOPES TO INCREASE YIELD PER TON.

CALUMET.—Slightly smaller 'rock' shipments by the Calumet & Hecla mines in January brought about a corresponding decrease in refined copper production for the month. The output of Calumet & Hecla proper, 4,671,200 lb., compared with 4,754,000 for December; Ah-meeek's production of 1,818,300, compared with 1,914,500; and 744,800 for Isle Royale with 845,800.

Calumet & Hecla continues to do all of its stamping in its Calumet mill, the Hecla mill remaining idle. Eleven heads are in commission. There is no immediate prospect of an increase in production. Unless there is a sharp rise in the metal market Calumet & Hecla mine output will be kept within the capacity of the one mill. No amygdaloid 'rock' is being stamped, the entire output coming from the conglomerate shafts.

The Stanton mines now have a complete underground force. Mohawk production has come up from 2400 to 2600 tons daily and Wolverine is shipping close to 1000 tons. Both mines are just about at the peak in production. All four heads in the Mohawk mill are being used on Mohawk rock, while two heads are in commission in the Wolverine mill. Not all of the Mohawk-Wolverine metal is being disposed of, much going into storage.

If Wolverine does nothing more than remove its shaft pillars it will require eight years or more to complete that work. Pillars are now being taken out on the 38th level. Operations on this level will not be completed until April 1. The work then will be started on the 37th. It is estimated that about three months is required to finish one level, and there are thirty-seven still to receive attention. In addition to removal of pillars, miners are engaged in cutting out arches, backs of stopes, and widening out drifts. The pillars are yielding good ore, running from 15 to 17 lb. per ton.

In connection with Isle Royale's plan to increase its yield of refined copper per ton of rock stamped, to enable it to reduce costs and better meet depressed metal market conditions, it is interesting to note what has been done heretofore in the way of close rock selection. In 1916 about 19% of the rock hoisted was discarded. The copper yield that year was 13½ lb. per ton. In 1917 the percentage of discard was raised to 23% and the yield increased to 14½ lb. In 1918 the discard was 18%. The average run of rock was much better in 1918 than in preceding years and required less selection. The yield was 16 lb. per ton. The improvement in ground continued in 1919 and with a 19% discard the yield was 18 lb. per ton. It is hoped now to bring the yield up to 20 lb. with closer selection.

Local mining men are inquiring into the provisions and purposes of a measure introduced in the State Legislature at Lansing to tax mines according to the actual value of all buildings above ground and all ore mined during the year, instead of on shafts and estimated value of property underground. It is suspected that this is a veiled attempt to enact a law providing a tonnage tax.

NEVADA

NEW BODY OF RICH ORE IN THE FLORENCE MINE IS OPENED.

GOLDFIELD.—The vein striking into the hanging wall of the Little Florence east vein that was opened recently in the Cracker Jack lease on the Florence has proved to be a cross-fissure leading to a vein 42 ft. in the hanging wall of the Little Florence east vein. The drift has been driven 20 ft. and the last sample of the face gave a return of \$84, according to R. C. McCarthy, superintendent of the Florence. A winze is being sunk in the cross-fissure. All of this work is being done at a depth of 500 ft. The orebody is the most important found in the Florence since the Florence Divide lease shoot was opened. Barker, Heiden, and Witt, working at a depth of 200 ft., will soon make a carload shipment of ore mined in the hanging wall of the Engineers' vein. Donald and Giles, at a depth of 358 ft. in the Reilly block, have 40 tons of ore saved and they expect to make a carload shipment of

work below the 60-ft. level will be done through the shaft now in use. The terms of the option are said to call for the sinking of a 30-ft. winze. The vein dips at 45° and the shaft is practically at the apex. All of the work to date has been done with hand-drills, but a two-drill air-compressor is in place and machine-drills will be in use in a few days. Harry MacNamara and others took a lease a few years ago and shipped 75 carloads of ore, stoping to within 10 ft. of the surface, 50 ft. from the present stope. Then came the Divide boom and MacNamara took an option on 650,000 shares of stock and re-organized the company into the Golden State. After the boom the Knox Divide took an option from MacNamara.

UTAH

UTAH CONSOLIDATED COMPANY FILES ACCOUNTING FOR ORE WRONGFULLY MINED.

The Utah Consolidated Mining Co., in accordance with

THE ROCHESTER 'COMBINED' MILL AT ROCHESTER, NEVADA

\$20 ore from screening stope-filling. An odd lease on the Consolidated is that of Charles Magee, who says he is making a fair profit in placer mining. He uses a rocker to wash gravel in one of the gulches.

PEAVINE.—A gold-silver-copper orebody 3 to 8 ft. wide has been drifted on for 100 ft. on the 300-ft. level of the Standard Metals.

COALDALE.—Goldfield men who visited the Darms coal mine and took a sample of the 2-ft. vein at a depth of 420 ft. had the coal tested by blacksmiths, who said it was better than the coal costing \$60 per ton they are using now. The coal is of poor appearance, but the blacksmiths say it is ideal for welding purposes, making a good weld and not coking too much. A 10-ft. drift is the only work done in this vein.

MANHATTAN.—The mill of the White Caps is not to be re-opened until mid-summer, instead of on March 1, as was reported, according to the latest official statement on the subject. Three shifts of miners are now employed.

KLONDYKE.—The stope on the 60-ft. level of the Golden State mine of the Knox Divide is 55 ft. long and the ore is being broken over a width of 7 to 11 ft. The stope is now 20 ft. high. Sinking of the winze from this level was discontinued at a depth of 30 ft. and, according to persons at the mine, it is improbable that further

a decree of the United States District Court, has filed an accounting and financial statement setting forth what it believes is the total value of ore extracted from workings of the Utah-Apex Mining Co. It amounts to 117,000 tons, and the Utah Consolidated states it mined and milled this tonnage at a profit of \$658,000. This is only 26% of the \$2,500,000 damages sued for by the Utah-Apex, which sum experts testified in court was a conservative estimate. It is not improbable that exceptions will be taken to this accounting by the Utah-Apex. According to returns filed with the State Board of Equalization, the Utah Consolidated company estimates the value of its properties, for taxation purposes, at \$778,010.

WASHINGTON COUNTY.—At the property of the Silver Reef Consolidated Mining Co. at Leeds, 40 men are now employed, the monthly payroll being \$5000. High-grade ore was found recently in the 'Honest' mine, at a depth of 150 ft., which assays as much as 300 oz. silver per ton. In the 'Robb' mine, the shaft is down to a depth of 200 ft., and is in ore averaging \$28 per ton. Plans are being prepared for working the old tailing at the Barbee mill-site. The tailing dump contains sufficient silver and copper to make it profitable. It is the intention to sink a shaft at the Thompson mine to drain the old workings. In the Leeds mine, an 8-ft. body of ore was cut at a lower

depth than any of the old-time workings in that property.

BEAVER COUNTY.—The Leonora Mining Co. drove 400 ft. of drifts, winzes, and raises during 1920. Some additional buildings were erected and machinery installed. The new shaft at the east end of the property was sunk to a depth of 135 ft. Some bunches of high-grade silver-copper ore have been found. Prospecting in the west end of the property resulted in finding ore averaging 7 oz. silver and 6% lead. This deposit has been opened for 60 ft. At the annual meeting of the stockholders, John Matson was elected president; B. H. Goddard, vice-president; H. E. Giers, secretary-treasurer; L. H. Stohr and J. W. Chase, directors.

EUREKA.—Imer Pett, general manager for the Bingham Mines Co., confirms the report of the discovery of ore rich in gold, silver, and lead in a cross-cut about 100 ft. above the 1550-ft. level in the Victoria mine. At the Eagle & Blue Bell, adjoining the Victoria and owned by the same interests, the most important piece of work is a drift being sent out from the 2000-ft. level. It is expected that within the next 300 ft. an ore-channel will be entered. During January these two mines shipped 92 cars of ore, and the February production is expected to exceed this.

All weekly records for ore production in the history of Eureka were broken during the week ending February 12, when a total of 193 cars of ore was shipped. The previous record was a total of 177 cars, made during January 1921. The Tintic Standard shipped 80 cars; Chief Consolidated, 36; Dragon, 19; Iron King, 17; Eagle & Blue Bell, 13; Victoria, 10; Grand Central, 5; Gemini, 4; Centennial-Eureka, 3; Bullion-Beck, 2; Iron Blossom, 1; Eureka Hill, 1; Gold Chain, 1; and Colorado, 1.

BRITISH COLUMBIA

NEW OIL-LEASING REGULATIONS ARE MADE BY CANADIAN GOVERNMENT.

VANCOUVER.—The western branch of the Canadian Institute of Mining and Metallurgy held a successful meeting February 9 to 11. Probably the greatest interest was in a coal symposium, in which many prominent coal-mine operators took part. It is generally felt that the high price of coal in Vancouver and Victoria (\$12 to \$14.50 per ton) is holding back industry and preventing the investment of capital in the Province. Charles Graham, of the Canadian Collieries, Ltd., blamed the present state of the coal-mining industry on Vancouver Island to the extensive use of fuel-oil, claiming that that commodity annually displaced some 600,000 tons of Vancouver Island coal, and at the present price of fuel-oil cost the Province \$6,000,000 yearly, which might better be spent in the development of the coal industry. George Wilkinson gave figures to show that the coal operators were making only about 40c. per ton of coal produced and that the retailers were making \$1.44 per ton of coal sold. He stated that the cost of lump-coal at the bunkers was \$8.71, and the cost of sacking and transportation to

Vancouver was \$4.35. Alexander Sharp, on the other hand, stated that in 1919 of the 2,267,541 tons of coal mined only 4.7% was won by machinery, and to this fact he attributed the high cost of production.

VICTORIA.—The Tidewater Copper Co. has shipped a diamond-drilling outfit to its Indian Chief mine, near Sidney Inlet, Vancouver Island. During the cessation of shipping, it is proposed to do considerable exploration with the drill.

The following new regulations governing oil-leases in the Northwest Territories have been received from Ottawa. These supercede all previous regulations and are retroactive to the beginning of the year. They provide for the granting of prospecting licenses for four square miles each, instead of three. In the event of discovery, the licensee will be allowed to take out a 21-year lease for an area of one square mile, the remaining three square miles held under the license reverting to the Government. No prospector is permitted to take out more than five licenses. Each license is for a period of four years, the rental for the first year being at the rate of 50c. per acre, and thereafter at \$1 per acre. An adequate drilling outfit must be installed on the location within two years of the application; drilling to a depth of 500 ft. must be accomplished by the end of the third year, and to 2000 ft. by the end of the fourth year. The penalty for non-compliance with these regulations is automatic forfeiture of license without declaration of cancellation on the part of the Crown.

ONTARIO

BULLION BEING STORED AT COBALT.

COBALT.—There has been little bullion shipped since the beginning of the year, operators hoping for an upward movement in the price of silver and storing their output. The men have apparently accepted without much protest the wage-cut of 75c. per day, which was to go into force on the 15th. They requested a modification of the cut, making the reduction gradual over a period of three months, but the operators declined to reconsider the matter.

The Nipissing during January produced silver to the estimated value of \$139,882 and cobalt valued at \$18,200.

Lateral work at the 410-ft. level of the Chambers-Ferland has opened up a strong vein carrying considerable smaltite. The strike of the vein is directly toward one coming in from the Nipissing and carrying high-grade ore on that property.

Work on the 5th level of the Bailey has opened up the new vein for about 80 ft. The vein averages two inches in width with high-grade ore in patches and three feet of wall-rock on each side is good milling material.

A Government bill now before the Ontario legislature imposing additional taxes on the profits of mining companies is meeting with strong opposition from mining men, as unfair and likely to discourage the investment of capital in the industry. It increases the tax on profits over \$10,000 per year from the present rate of 3% to 4%, and when profits exceed \$1,000,000, from 5% to 7%.

COINAGE OF SILVER DOLLARS RESUMED

The first new silver dollars put in circulation since 1905 were coined at the Philadelphia mint on February 19. This is in pursuance of the terms of the Pittman Act, which provided that the Secretary of the Treasury might melt up and sell a maximum of 350,000,000 silver dollars but that he should purchase sufficient silver to replace the coins. The re-purchase price was fixed at \$1 per ounce and it is this silver, obtained from domestic producers, that is being coined at the present time. Approximately 207,000,000 oz. will be purchased for the purpose.

SERIOUS FIRE AT BROKEN HILL SMELTERS

The 'Financial Times' of London says:
"From the latest cabled advices the fire at the works of the Broken Hill Associated Smelters, situated at Port Pirie, Australia, indicate—although nothing has yet come to hand from any of the companies concerned—that the matter is much more serious than the first message suggested. According to Reuter's Melbourne correspondent, the damage done may reach £250,000, the works may have to be closed for an indefinite period, and it may, therefore, be necessary to suspend productive operations at the famous Broken Hill silver-lead-zinc field of New South Wales. This field has been veritably the sport of fate since the Armistice, for it was only last November that the eighteen months long strike of miners was settled. No sooner did the men return to work than the prices of metals went so low that the mines had to curtail production severely. The one relief to the present situation is that the temporary cutting-off of Broken Hill lead and zinc supplies should accelerate a recovery of the quotations on these metals, and a similar cause may even help the silver quotation. Unfortunately the five leading Broken Hill companies which co-operatively own the smelters are understood to carry their own insurance."

ALLOTING THE EXPORT COPPER

Through its purchase of 400,000,000 lb. of copper the Copper Export Association has become the owner of the greatest tonnage ever under one control. It was bought for re-sale to foreign consumers only and not a pound can be sold for domestic consumption. Although a large number of individual mining companies have membership in the Export Association, the greater part of the business has been in the hands of a committee representing the four largest sales agencies. The contributions to the 400,000,000-lb. pool may thus be summarized:

Agency	Interest, %	Pounds
Guggenheim Brothers	38.90	155,600,000
Anaconda	31.50	126,000,000
Phelps Dodge Corporation	10.90	43,600,000
Calumet & Hecla	6.00	24,000,000
American Smelting & Refining Co.	5.00	20,000,000
United Verde	5.00	20,000,000
Miscellaneous	2.70	10,800,000
	100.00	400,000,000

These figures give an idea as to the proportions in which the country's copper surplus has been held and indicate, furthermore, that when the American Smelting & Refining

Co. at the first of the year turned over to the Guggenheim Bros. its agency business there went with it upward of 200,000,000 lb. of copper.

EARNINGS OF THE INTERNATIONAL NICKEL CO.

Earnings of the International Nickel Co. in the third quarter of its fiscal year ended last December showed the full effects of the industrial depression, profits declining in a sharp manner. These decreased earnings, however, are simply in line with those of other companies, as International Nickel had to absorb inventory losses which, with smaller business, accounts for the relatively poor showing. Starting out in the first three months of its year, the company showed a surplus after preferred dividends of \$1,268,000, and in the second quarter reported \$726,000, a total for the half-year of \$1,994,000. Now for the nine months the surplus after preferred dividends totals but \$2,219,000, indicating that in the three months ended December last the company had a balance of but \$225,000. This severe shrinkage in profits, as pointed out above, may be mostly traced to losses which were absorbed from inventories.

On the outstanding \$41,834,600 common stock the company shows a balance of \$2,219,000, equivalent to \$1.33 per share on a par value of \$25, or 5.32%. Based on the results up to last December earnings for the common stock were running at the annual rate of \$1.76 per share. In view of the general depression which exists at the present time it is not to be expected that the above sum will be realized. While optimistic prospects were held out early last year for the resumption of common dividends, recent events have, for the time being, made this expected action remote.

COPPER PRODUCTION OF THE PORPHYRY COMPANIES

Official estimates place the January production of seven of the prominent 'porphyry' companies at 28,042,744 lb., a drop of 6,819,040 lb., or 20%, as compared with January 1920, and of \$11,659,516 lb., or 29% decrease, as compared with that month of 1919. In December of last year these same producers turned out 28,535,579 lb. New Cornelia was largely responsible for the January increase over December, the other companies making practically unchanged production for both months. The combined monthly production of this group of companies in January averaged at the rate of but 336,504,000 lb. per annum, or about 50% of combined production during the last war year, when these companies turned out 627,832,000 lb., and compares with 407,328,000 lb. in 1919, and 422,137,000 lb. last year.

The following figures show the production of refined copper during January of the past three years, the figures being in pounds:

	1921	1920	1919
Chino	2,999,751	3,081,937	4,241,000
Inspiration	5,000,000	7,200,000	6,500,000
Miami	4,389,993	4,461,247	5,273,260
Nevada Con.	3,000,000	4,181,938	4,400,000
New Cornelia	2,170,000	3,354,000	4,318,000
Ray	2,983,000	3,889,073	4,470,000
Utah	7,500,000	8,693,589	10,000,000
Totals	28,042,744	34,861,784	39,702,260

HEARINGS ON FREIGHT-RATES ON COPPER FROM UTAH TO PACIFIC PORTS

Final arguments were completed on February 17 at Salt Lake City in the hearing conducted by examiners of the Interstate Commerce Commission to determine the reasonableness of the rate of \$6.50 per ton on copper ingots from Utah points to San Francisco, where it is to be loaded on boats for shipment to the Atlantic seaboard by way of the Panama Canal. The rate was published in December, but the Interstate Commerce Commission ordered it withdrawn, pending a hearing. It is stated that the Commission will file its order in the matter on or before April 29. If the rate is allowed to stand, it will result in a saving of \$6 or \$7 per ton over the present all-rail route to New York.

ARIZONA

Jerome.—It has been announced that sufficient capital has been secured to continue exploration at the Shea mine. The shaft is to be sunk to the 1000-ft. level and the orebodies cut in the tunnel on the 535-ft. level are to be developed.

Kingman.—F. P. Aylwin and associates have taken over the American Flag mine and operations are to commence immediately. The deposit was discovered in 1876 by William Shoulters who sunk a 60-ft. shaft and shipped ore to Wales. He later sold the mine for \$25,000. The property was then developed to the 250-ft. level and over \$400,000 in silver was taken out and shipped to Wales.—Kent Keller has adjusted all the litigation concerning the title of the old White Hills mine in the Cerbat range and expects to open the mine soon. The White Hills mine was operated continuously for nine years in the 'nineties by an English company that erected a 40-stamp mill and, it is reported, took out over \$6,000,000 in silver.

Phoenix.—Upon his return to the Relief gold mine property, 25 miles north-west of here, George Hammond, superintendent, discovered that several large frame buildings, the hoist, steam-engine, and hoist-house had all been stolen from the property. Large motor-trucks had, apparently, been used for the purpose.

Tombstone.—It is announced by James Kelly that following an examination of his silver-manganese property in Miller canyon in the Huachuca mountains by Eastern capitalists, a company is to be formed immediately to take over his group of claims and an adjoining group. The property has been worked in a small way for a number of years.—The number of mines working in the Tombstone district has increased in the last six months. Many of the old properties are being worked by lessees and are reported to be doing well. At present four mills are being re-built or are under repair. Joe Rest is erecting a small mill on his claims and the Old Guard mill is being overhauled preparatory to starting up next month. A new mill is being erected by lessees near the State of Maine mine and Bert Holland's new mill is expected to be started immediately.

CALIFORNIA

Calaveras County.—It is reported that a 6-ft. vein of gold-bearing quartz has been uncovered on the 200-ft. level of the Angels Camp Deep mine. A cross-cut is being driven on the 500-ft. level to intercept the same vein. The head-frame at the shaft is being repaired and the stamp-mill is nearly ready for operation.—The downward continuation of the productive 'Flat' lode has been found on the 1150-ft. level of the Carson Hill mine. The orebody recently opened on the 1600-ft. level contains good milling ore over a width of 12 to 15 ft. The 10 additional stamps recently started will bring the capacity of the mill to 500 tons per day, when it is expected that lower-grade ore can be profitably treated.

Eldorado County.—The orebody recently opened on the 250-ft. level of the Buckman mine, being operated by the Grit Mining Co., proves to be a valuable discovery. Milling

machinery is being sent to the property.—The Eldorado Mines Association has been formed with the object of settling litigation that has hampered operations in the district for many years.

Nevada County.—The inclined portion of the Idaho-Maryland shaft at Grass Valley has been unwatered to within 200 ft. of the bottom. The company is said to have completed arrangements for developing the Grasshopper claim, in which the extension of rich veins is expected to be found.—The largest production since the curtailment during the War is being made by the North Star company. The central mill is running steadily.

Placerville.—The Pacific Channel mine, 18 miles east of here, is being developed by J. E. Sexton, of Palisade, Nevada. An adit is being driven that has opened the channel for a distance of 150 ft., the gravel containing as much as \$1 per yard in gold.

COLORADO

Central City.—The Cornucopia Leasing, Mining & Milling Co. is developing two strong veins that are thought to be an extension of the Perigo vein system. John Havens, of Denver, is president of the company.—The Buell plant, of the American Mines & Development Co., is being overhauled and will resume operation about March 1. Ore from the East Boston mine will supply the mill.

Debeque.—Shale-oil is being successfully retorted at the plant of the Mount Logan Oil Shale Co. Two other plants in the vicinity are reported to be nearing completion. The Monarch Oil Shale Co. and the Index company both have plants nearly ready to operate. Carl Schuyler is erecting a plant near Grand Valley, Colorado.

Denver.—Public hearings, investigating the affairs of the Colorado School of Mines at Golden, are being held before a joint Legislative committee. The hearings are open to the public. Victor C. Alderson, president, against whom most of the criticism has been directed, answered the charges made against his administration.

Leadville.—Following the issuance of a charter for the Leadville Mine Development Co. by the Secretary of the State, Leadville citizens are responding liberally and \$8000 was subscribed in the first two hours, when John Cortellini passed the subscription list. The following men have been elected directors: Jesse F. McDonald, former governor, Ezra D. Dickerman, John Cortellini, William Harvey, and Joseph W. Clarke. Martin Kieff, of the firm of Platt & Kieff, has been engaged to survey the tunnel site, and the starting of the tunnel to tap the expected wealth of Prospect mountain and Canterbury hill, will start soon.

IDAHO

Coeur d'Alene.—The Reed Level Mining Co. is employing 25 men in mining and milling operations. The company was formed by consolidating the interests of the Co-operative mill at the entrance of the Reed adit to the Bunker Hill & Sullivan mine, and the holdings of a number of the lessees, granted them upon the upper workings of the mine. Improvements made in the mill consist of a flotation unit adequate to handle the slime derived from concentrating 200 tons of ore daily. An apparatus has been installed that dries slime concentrate by rabbling over a steam-heated manifold. Three stopes are being worked, producing 60 tons of ore per day.—The Western Union Mining Co., controlled by Spokane men, has just received a return of \$2544 per car on six carloads of ore sent to the East Helena smelter. The property is situated in Revenue gulch, two miles north-west of Wallace, and is being operated by lessees under a 25% royalty. A body of high-grade silver-lead ore has been blocked out.—On account of high freight-rates from Kellogg to the Eastern seaboard the Bunker Hill smelter is now shipping pig-lead to New York by way of Seattle and

the Panama Canal. Recently 1000 tons of pig-lead from the Bunker Hill was loaded at Seattle, and, unless there should be a substantial reduction on the bullion rate to the East by the railroads, officials of the company state that shipments by way of the canal will continue. The Bunker Hill company is the first to ship lead by water. Native silver in a rich vein of ore has been found in the Bluebird property on Blacktail mountain. The ore is similar to that on the Jim Evans property near by.—A three-mile wagon-road in the Idaho-Northern property, north of Murray, has been completed. When the compressor is installed a crew of men will start driving the adit on the property forward 1600 ft. to cross-cut the vein. When the vein is intersected a depth of 1000 ft. will be secured.—Development of the property of the St. Louis & Idaho Mining Co., near Burke, is to be resumed during the coming spring. Development work already done at the property consists of 1500 ft. of underground workings. No. 1 tunnel was run in 600 ft., disclosing considerable ore of fair grade.—Eight carloads of mining machinery, including a 50-ton ball-mill, large compressor, flotation plant, motors, and mine-cars, now at the Empire Copper mine, have been purchased by Fred Lee of the Hallidie Machinery Company, of Spokane. Work of dismantling will be started at once. The property is better known as the Horst-Powell.

MONTANA

Adair.—The Montana-Idaho Copper Co. is extending a 7000-ft. prospect-tunnel, which ultimately will attain a length of 9000 ft. The company has taken over the property formerly owned by the Monitor Mining Co., consisting in all of 44 claims. Ore assaying 15% copper and \$5 gold per ton was shipped by the Monitor company.

Butte.—Anaconda now has workings in practically contiguous property along the strike of the great vein system for a distance of about six miles, in consequence of its acquiring a joint ownership with Beer, Sondheimer & Co., in the latter's Missoula gulch territory, which is situated in the west-central part of the district.—Operations at the No. 3 shaft of the Black Rock mine are giving promise of a large tonnage, comparable with that had on the upper levels. This shaft is being sunk in the Rainbow vein, which dipped into the shaft below the 2400-ft. point. Butte & Superior has about 50 men engaged in development and improvement work.—East Butte is operating but one shift in its Pitts-mont mine and one furnace in its smelting plant. The proposed curtailment of operations in its flotation plant from seven to five days weekly is not due to a reduction in its own production, but is the result of the curtailment put into effect by the Davis-Daly Copper Co., which has reduced its daily output from 300 to 200 tons. The capacity of East Butte's flotation mill is 600 tons per day.

Helena.—A new law, signed by the Governor, makes it obligatory on owners of mines to settle with lessees on their properties within seven days after returns have been received from the smelter. A penalty of 10% of the net returns is imposed. It is said that some lessors have waited as much as six months before making settlements with their lessees. The same bill requires that the owner furnish the lessee with an accurate copy of the smelter returns.

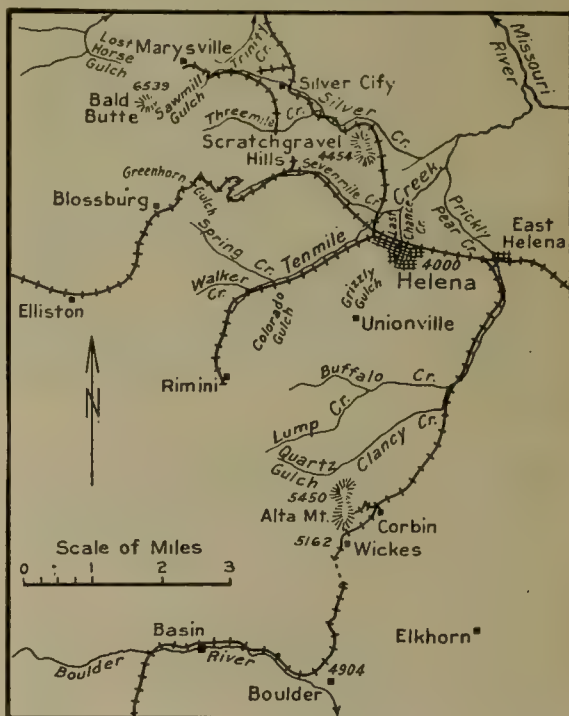

Neihart.—At the Hartley mine a 2-ft. vein of ore assaying 80 oz. of silver per ton and containing \$15 in gold has been discovered. The ore is peculiar for the reason that most of the ores of the district contain little of any valuable metal other than silver and lead.

Scratch Gravel.—J. L. Howard, of Spokane, has acquired a number of claims. Three of these—the Champion, Silver Edge, and Aster—have produced rich ore. The other claims, known as the Benton, Defender, Alabaster, and Stark, are likely prospects. The ore is low-grade lead-silver, with some copper.

Sildix.—Good progress is being made in unwatering the 400-ft. shaft of the Amazon-Dixie mine. The shaft will be sunk an additional 400 ft. Likewise a 2000-ft. adit will be extended into the Leslie Grant, which was recently acquired by the Amazon-Dixie company. Eighteen men are employed at the property.

NEVADA

Eureka.—High-grade ore on the 400-ft. level of the Eureka-Holly mine is reported. The discovery was made several hundred feet from the known ore-shoots. The volatilization furnaces at the Holly reduction plant are completed. A trial run will be made at once.—D. States reports that progress is being made in driving the main tunnel of the Uncle Sam Consolidated. The vein in the upper workings contained ore worth \$160 per ton. As many miners as can conveniently work in the tunnel are employed.—A

HELENA, MONTANA, AND NEIGHBORING MINING DISTRICTS

drift from No. 8 winze of the Eureka-Croesus has exposed ore for a distance of 25 ft. This ore is found on a lower horizon than any of the old or recent shoots in the mine.

Gold Circle.—The Elko Prince has opened a shoot of ore for a distance of 100 ft. on a vein measuring from 20 in. to 4 ft. wide. The ore averages \$200 per ton.—Berry Brothers have exposed a 6-ft. vein of \$115 ore at a depth of 220 ft. in the Big Chief group.—The extension of the electric-power line from Battle mountain is projected and it is hoped to have the line built this year.

Good Springs.—The experiments being conducted by the Bureau of Mines, at Salt Lake City, on ore from the Yellow Pine mine show that 94% of the silver and 80% of the lead can be obtained by use of the chloride-volatilization process. Experiments on a large scale at the plant here have verified laboratory tests.

Osceola.—Gold ore assaying from \$50 to \$60 has been found on the Crescent claim and is being worked by James and Jack Merritt. The ore was opened in a winze from the main tunnel. Osceola was at one time one of the richest gold-producing districts in Nevada.

OKLAHOMA

Picher.—A fund is being raised for the purpose of relieving suffering among the families of miners who have been thrown out of employment by the recent shut-down. The local sections of the American Zinc Institute and the American Mining Congress are co-operating in the work. Steps are being taken to afford employment on road building and other public work pending the revival of activity in mining, which is contingent upon improved prices for the metal. Development work is being done on a curtailed scale.

OREGON

Medford.—Under the initiation of Henry M. Parks, of the Oregon State Bureau of Mines, a meeting of mining men from the Blue Ledge district in north-western California and south-western Oregon, Gold Hill, Jacksonville, and the Applegate districts in Oregon, was held on February 11. The meeting was devoted to an open discussion of ways and means for continuing the existence in a revised form of the War Minerals Relief Commission, which under present rulings will terminate with the current administration. With this in view, resolutions were adopted favoring prompt action on a bill passed by the Senate and awaiting action of the House of Representatives, which provides for continuance of the War Minerals Relief Commission with revised scope of authority which would allow appeals from the action of the Commission to be made to the United States Court of Claims. The meeting went on record as opposed to the dilatory and entirely unsatisfactory methods by which the present War Minerals Relief Commission handled the claims presented from this particular section. An informal discussion on the possibilities for a protective tariff on manganese and chrome minerals brought out the fact that the local mining opinion was strongly in favor of such legislation.

WASHINGTON

Spokane.—The Northwest Mining Convention, to be held at Spokane, Washington, February 28 to March 5, is expected to be the largest ever held. A special committee has been appointed to make the visitor's stay in this city one to be remembered. Theatrical parties, luncheons, and various other entertainments are being arranged for the comfort of the visitors.

MEXICO

Chihuahua.—H. Sulliger, manager for the Dolores Mines Co., has returned from a trip to the Mineral de Dolores, west of Temosachic, in the Guerrero district, near the border line between Chihuahua and Sonora. The corporation represented by Mr. Sulliger intends to invest \$1,500,000 in the erection of a new mill at Dolores and in a power-plant at Madera, also starting the operation of the rich gold-silver mines in that mining camp. The wagon and automobile road between Dolores and Madera station has been repaired and is ready for traffic.

Guanajuato.—The Guanajuato Consolidated Mining Co. has decided to shut-down its mines and mills pending an improvement in the market for metals. About 400 men will be thrown out of employment.

ONTARIO

Porcupine.—During 1920 the Hollinger Consolidated Gold Mines Co. produced \$6,932,628 as compared with \$6,722,267 in the preceding year. After payment of dividends, the surplus remaining was \$461,275 as compared with \$1,232,109 in 1919.—The new part for the underground crusher at the Dome mine has been received and put in place. This single piece weighed nine tons and its replacement makes possible the supply of mill-ore at the maximum capacity. It is expected that the supply of hydro-electric power will be plentiful as soon as the weather breaks, and production should then be increased.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Edgar Rickard is at Duluth.

Philip Argall is in Washington.

F. M. Mechling is here from Tonopah.

Morton Webber is at the Palace Hotel.

Algernon Del Mar is at Nayarit, in Mexico.

E. Coppee Thurston is at the Hotel Darby, Los Angeles.

Thomas B. Stearns, of Denver, is expected here this week.

Geo. Watkin Evans, of Seattle, was in San Francisco last week.

Charles R. Keyes, of Des Moines, is on his way to the west coast of Mexico.

Arthur Winslow sails on February 28 from Boston for Liverpool on his way to Spain.

Frank G. Janney and Charles W. Stimpson, both of Salt Lake City, were here last week.

F. R. Raiff, traffic manager for the American Smelting & Refining Co., is at Salt Lake City.

D. D. Moffat has returned to Salt Lake City after a trip to the Mesabi iron property in Minnesota.

Philip Wiseman has been elected a vice-president of the Chamber of Mines and Oil, at Los Angeles.

George W. Heinz, of the United States Smelting, Refining & Mining Co., has arrived here from Boston.

Charles N. Edge, of New York, is visiting his mine at Chinese Camp, on the Mother Lode, California.

H. D. Pallister has been appointed Professor of Mining in the School of Mines of the University of Alabama.

William Frecheville, formerly Professor of Mining at the Royal School of Mines, London, was in New York last week.

C. B. Lakenan, general manager for the Nevada Consolidated Copper Co. at McGill, was at Salt Lake City recently.

Sherwood Aldrich, president of the Ray Consolidated Copper Co., is making an extended trip to Japan, China, and the Philippine Islands.

H. W. Edmondson left New York on February 19 for Mexico, where he will make an examination of the Rio Plata mine, at Guazapares, Chihuahua.

Walter Fitch, president of the Chief Consolidated Mining Co. at Eureka, Utah, is in southern California. Cecil Fitch, manager for the same company, is at Honolulu.

H. C. Bellinger, vice-president of the Chile Copper Co., and Fred Hellman, consulting mining engineer for Guggenheim Brothers, were in Utah recently, visiting metallurgical plants.

William E. Colby has returned from Kingman, Arizona, where he argued the case of the plaintiff in the apex suit, Tom Reed v. United Eastern. John P. Gray, of Coeur d'Alene, represented the defendant.

Ralph R. Woolley, hydraulic engineer with the U. S. Geological Survey at Salt Lake City, is in Washington. He has been collecting data for a publication on the 'Water Powers of the Great Salt Lake Basin', to be published by the Survey.

J. C. Dick, chief of the sub-division of natural resources of the Internal Revenue Income Tax Unit at Washington, D. C., has resigned, effective March 31. Mr. Dick will resume his profession of consulting mining engineer at Salt Lake City. His successor is C. F. Powell, of Oklahoma City.

COPPER		MOVEMENT OF GOLD AND SILVER	
Prices of electrolytic, in cents per pound.		Imports of gold into the United States for the calendar year totaled \$428,700,000, compared with \$78,500,000 for the calendar year 1919, while gold exports aggregated \$322,100,000, against \$368,200,000 exported in 1919, according to Federal Reserve Board estimates announced on February 15. Practically no change for the year was shown in gold-reserves of Federal Reserve banks, notwithstanding the record volume of gold shipments.	
Date Feb. 15..... 13.00 " 16..... 13.00 " 17..... 12.75 " 18..... 12.75 " 19..... 12.75 " 20 Sunday..... 12.75 " 21..... 12.75	Average week ending Jan. 10..... 12.87 " 17..... 13.08 " 24..... 13.00 " 31..... 12.75 Feb. 7..... 12.87 " 14..... 13.00 " 21..... 12.83	Silver imports in 1920 totaled \$88,100,000, compared with \$89,400,000 in 1919, while silver exports for the year were \$133,600,000, compared with \$239,000,000 exported during the preceding year. Net silver exports for the year totaled \$25,600,000 against \$149,600,000 in 1919. More than 60% of the incoming silver shipments was mined in Mexico, while an additional 13% came from Peru. Of the total silver exports for the year, more than 84% was consigned to the Far East, China receiving more than one-half of the total outgoing shipments, while British India was another big consignee.	
		THE PRICE OF REFINED OIL	
		A prominent oil-refiner says no radical reduction in the price of refined oil is expected for several months. Some refiners carry stocks of crude oil five and six months ahead, many at least a three months' supply. This oil has been purchased at high prices, and until these stocks are disposed of no material reduction in prices of the products is expected. The labor situation is more important in refining than in production, and wages have not gone down materially in refining from the high mark of 1920. Although demand for oil products is not large, refiners are expecting a heavier demand shortly, probably by April.	
		BRITISH GOLD PRODUCTION	
		A preliminary report on gold production of the British empire for 1920 in the 'Mining Journal' of London shows a general decline, as compared with the output of the previous year. The Transvaal, Western Australia, Rhodesia, India, Queensland, and New South Wales reported decreased production while Victoria's output was 152,702 oz. as compared with 135,427 oz. in 1919. The grand total for all British goldfields is given as 10,091,078 oz. in 1920.	

LEAD		MALAY GOVERNMENT FIXES PRICE OF TIN	
Lead is quoted in cents per pound, New York delivery.		Owing to the constantly fluctuating price of tin, the government of the Federated Malay States, says a consular report, has made arrangements to purchase tin at \$110, local currency, per picul of 133 1/3 lb. The Straits Trading Co. and the Eastern Smelting Co. are to act as purchasing agents on behalf of the Government. It should be noted that this price does not refer to tin ores but to smelted tin only and will vary as conditions change.

Eastern Metal Market

New York, February 16.

There is little animation to any of the markets, but an optimistic tone is evident in nearly all. Prices are fairly firm to steady in most cases.

The copper market is stronger after the settlement of the project to finance the surplus stocks.

The tin market is moderately active with prices fairly steady.

Demand for lead is only light with the price tendency downward, if anything.

There is still almost no buying of zinc, but prices are fairly steady.

IRON AND STEEL

The price developments reveal a further downward tendency. Steel is obtainable \$5 below the Steel Corporation levels and basic pig-iron has also sold at lower levels. The effect has been to postpone further buying of steel and also to curtail operations. In fact it is probable that actual buying is below one-fourth of the country's capacity.

There is no prospect of any early revival. Production will probably recede rather than advance in the next few weeks. General conditions are, however, regarded favorably and optimism as to the future is not wanting.

Wage reductions continue, but not by the Corporation. In the Youngstown district a 20% reduction has been announced.

Finished steel and some semi-finished is now to be secured quite generally at \$5 per ton under the Steel Corporation prices. In steel-making pig-iron, basic has sold \$5 down or at \$25, Valley.

In the export market the feature is the continental competition for the present small volume of business.

COPPER

There has been a distinct improvement in inquiry and the market is gradually developing a considerably firmer tone. This is due probably to the announcement of the successful financing of the copper surplus of 400,000,000 lb. by the sale of debentures amounting to \$40,000,000. This virtually removes this large quantity from the market so far as its being a drag, for it is held largely for export and is to be sold at not less than 12.50c. per pound. Quotations for electrolytic copper are firm at 13 to 13.25c., delivered, with some producers asking 13.25c. as a minimum. Lake copper is firm at 13.50 to 13.75c., delivered. There is an inquiry for 2000 tons from Italy and various consuming interests, who evidently are commencing to feel the market, represent requirements up to 9,000,000 lb., the bulk coming from brass-making interests.

TIN

Interest in this market has fallen to a low ebb. The market is quiet, almost to stagnation. Whereas dealers were buyers recently, they are now uninterested and so are consumers. It is now confirmed that the Malay government has reduced its minimum price to £203 at which it will purchase metal from producers. The New York market for spot Straits has clung close to 33c. the past week, the quotation yesterday having been 32.50c., New York, with almost no business to establish a market. London, however, is higher than a week ago by £6 to £8 per ton. Spot standard was quoted yesterday at £170 per ton, future standard at £173 10s., and spot Straits at £190. Arrivals thus far this month have been 1520 tons with 2225 tons reported afloat.

LEAD

Apparently the present demand can easily be satisfied with metal at 4.70c., New York, or 4.35c., St. Louis, which

are the levels in the outside market. The market is quiet and extremely dull and devoid of new features. The leading interest continues to quote 4.75c., New York and St. Louis, a level it has maintained for a month or two. Production in lead is now heavier than market conditions really warrant because of the price of silver, which makes it profitable and desirable to work some mines that otherwise could not be operated now.

ZINC

This market continues its listless lifeless course. Sales are small and confined to the immediate needs of regular customers. Despite the lack of improvement prices remain fairly firm at 5c., St. Louis, or 5.50c., New York, for the domestic metal, while imported zinc is quoted at 5.35c., seaboard. Reduction in production is reported as progressing further. Prospects for the future are not encouraging as to a renewal of normal activity.

ANTIMONY

There is no change in this market, wholesale lots for early delivery being quoted at 5.25c., New York, duty paid, with jobbing lots about 4c. per pound higher.

ALUMINUM

Virgin metal in wholesale lots from the leading producers is quoted at 28.20c. per pound f.o.b. plant, while the same grade from other sources, handling the foreign metal, is obtainable at 24 to 25c. per pound, New York.

ORES

Tungsten: No improvement is reported and the market remains unchanged. Offerings of ore at \$2.75 to \$3 per unit are noted but there have been no sales.

Ferro-tungsten is quoted at 58c. per pound of contained tungsten, guaranteed as to quantity; the non-guaranteed material is held at 38c. Powdered tungsten is quoted at 70 to 77c. per pound of contained metal.

Molybdenum: Quotations continue nominally unchanged at 60c. per pound of MoS₃ in regular concentrate. There is no demand.

Manganese: The market is devoid of feature or demand with quotations nominal at 35 to 40c. per unit, seaboard, for high-grade ore.

Manganese-Iron Alloys: Ferro-manganese can be obtained now from American producers at \$100, delivered, while the British alloy is quoted at \$100, seaboard, but there is no demand to test the market, except an inquiry for export of 600 tons to Japan with little prospect of a sale. Spiegeleisen is quoted at about \$40, furnace, with sales of about 150 tons noted.

WAR DEPARTMENT WILL DISPOSE OF BRASS

The War Department will soon probably announce disposition of 56,000,000 lb. of brass, for which it received 50 bids recently. Brass is composed of two parts of copper and one part of zinc, so that the metal content of the above quantity would approximate 19,000,000 lb. of zinc and 37,000,000 lb. of copper.

The big quantities of brass, either new or 'junk', which have been available here and in Europe since the Armistice have been a handicap with which the copper producers have had to contend. During the past year over 100,000,000 lb. of brass was bought by American manufacturers abroad and brought back here to be re-melted. Both the War and Navy departments have also from time to time offered surplus stocks of brass on the market, thereby affecting detrimentally the market for the constituent metals.

Book Reviews

Coal Washing. By Ernst Procaska. 382 pp., 5½ by 8 in., 202 ill. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

A systematic description of modern practice in the art of coal-washing, containing the necessary information to enable the coal-operator to choose the apparatus and adopt the methods best adapted to his requirements.

Electrolytic Deposition and Hydrometallurgy of Zinc. By Oliver C. Ralston. 210 pp., 6 by 6 in., 46 ill. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

This book has been written to describe present practice and the theory underlying the leaching of zinc ores, and the purification and the electrolysis of solutions. The author, who is metallurgist with the Hooker Electrochemical Co., of Niagara Falls, discusses the history of zinc hydrometallurgy, the roasting of zinc ores, leaching, purifying and electrolysis, chlorinating zinc ores, the electrolysis of zinc chloride, electrolytic zinc refining, melting electrolytic zinc, and the economics of zinc hydrometallurgy. A number of examples of current practice are described; and although the process is at an early stage of development the treatise will be welcomed as a useful guide to those interested in the subject.

Labor's Crisis. By Sigmund Mendelsohn. 171 pp. The Macmillan Co., New York. For sale by 'Mining and Scientific Press'. Price, \$1.50.

The sub-title of this book is 'An Employer's View of Labor Problems'. It consists of about twenty-five essays on various economic and sociological subjects ranging from 'Poverty, Its Nature and Effect' to 'Can Reduced Hours Advance the Welfare of Labor and of Society?' The author expresses opinions both on controversial questions and on questions on which there is general agreement. These opinions are supported by some statistics, but, otherwise, there is nothing in the body of the book or elsewhere to explain why the author reached his conclusions. Herein, rather than in the text itself, lies the chief weakness of the book. It can be recommended only to those who would like to read the unsupported conclusions of a man without any general reputation.

Applied Colloid Chemistry. By Wilder D. Bancroft. 345 pp., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

Professor Bancroft has succeeded remarkably well in collecting and classifying over fifteen hundred extracts from the writings of nearly one thousand authorities and investigators on practically every phase of colloid chemistry. The extracts have been arranged in orderly sequence and, in combination with subject matter introduced by the author, form a valuable contribution to the available literature on the subject. In his introduction, the author deals with the advance in the conception of colloidity, pointing out that a colloidal state is now usually referred to, and not a colloidal substance. Ostwald's definition is quoted in which the contention is advanced that a phase may be termed colloidal provided it is sufficiently finely divided or dispersed, without definite commitment as to what degree of subdivision is necessary in any particular case. In Chapter I the author deals with the adsorption of gas or vapor by solid. Many interesting data have been collected on the adsorption of various gases by charcoal, a subject brought to the front during the War by the need for efficient equipping of masks to purify air containing poisonous gases. Several of the

principal contact processes are also described. In Chapter II, other types of adsorption are considered, followed by a chapter on adsorption from solution, which contains a reference to a book of Defoe's in which mention was made of the 'filtering' of alkaline water by means of sand—an early record of an adsorbent effect. Surface-tension, the Brownian movement, and coalescence are considered in detail. Data on the preparation and properties of colloidal solutions have been classified and presented in condensed form. The book concludes with chapters on gelatinous precipitates and jellies, emulsions and foams, fog and smoke, gases and solids in solids, and the thickness of surficial films.

Revision for a second edition will doubtless disclose the fact that an abnormal number of compositor's errors on p. 312 have escaped the notice of the proof-reader. The adoption of the recognized abbreviation for 'gram' (gm.) is to be recommended. On p. 26, for instance, the abbreviation 'g', with and without the period, is used. The result of the innovation is that on p. 28 we read that "R. B. Loeb's finds that the adsorption of methyl alcohol vapor by 0.41g platinum black causes . . ." Coco-nut, a word that occurs frequently, is mis-spelled coconut, inviting confusion with 'cocoa', with which it has no connection. Such criticisms, however, may be deemed captious; but they indicate at least that minor points only are alluded to and so emphasize the fact that the book is timely and reliable, its preparation evidently involving a considerable amount of labor. It should prove of value to the technician as well as to the student.

*In addition there was a payment of \$600,000 made on July 3, 1919, to the Kerr Lake Mines, Ltd., as a return of capital to the stockholders of that company.

†In addition \$1,652,280 was paid by individual companies prior to the amalgamation in 1914.

Company Reports

CHIEF CONSOLIDATED MINING COMPANY

Report for the year ended December 31, 1920.

Property: Eureka, Utah.

Operating Officials: Cecil Fitch, general manager; J. Fred Johnson, superintendent.

Financial Statement: yield from production, \$2,242,708.58; net profit on operation, less Eastern office expense, \$328,881.37.

Dividends: 1920, \$353,792.80; February 1, 1921, \$44,201.60; to date, \$1,915,719.27.

Development: 23,801.9 ft., 2000 ft. less than 1919.

Production: 82,430 tons of ore of an average gross value of \$47.29 per ton.

TOMBOY GOLD MINES COMPANY, LTD.

Report for the year ended June 30, 1920.

Property: mines and mills at Telluride, Colorado.

Operating Officials: J. S. Peterson, general manager; W. K. Betty, metallurgical adviser.

Financial Statement: written off for property, plant, and machinery, with taxes paid and reserved, \$37,996 17s. 7d. Deducting balance carried forward from last year, leaves a debit balance of \$21,581 8s. 2d.

Development: very little done during the year. Ore-reserves, 888,244 tons.

Production: 146,066 tons ore was milled, producing bullion of the value of \$811,989.55.

The new plant commenced operations, as to one unit, for

five days in December 1919; and in January 1920 the full plant was put into commission. Unfortunately all the months in the latter half of the year, with the exception of March, have shown losses in working, in part owing to other causes, but principally to the difficulties of starting the new plant, and the adjustment of the treatment of the different ores in the mine.

BROKEN HILL PROPRIETARY COMPANY, LTD.

Report for the year ended May 30, 1920.

Property: Silver-zinc-lead mines at Broken Hill, iron mines at Iron Knob, South Australia, and steel works at Newcastle, New South Wales, Australia.

Operating Officials: G. D. Delprat, general manager; E. J. Horwood, works manager at Broken Hill; R. T. Slee, mine manager.

Financial Statement: The net profit for the year amounted to £517,663 3s. 2d., from steel-works operations.

Owing to the strike, which began on May 5, 1919, no work of a productive character has been carried on throughout the year.

MCINTYRE PORCUPINE MINES, LTD.

Report for the year ended June 30, 1920.

Property: mines and mill at Schumacher, Ontario, Canada.

Operating Official: R. J. Ennis, general manager.

Financial Statement: An operating profit of \$1,051,404.13, and a non-operating profit of \$228,828.24, were earned during the year.

Dividends: \$546,042.45.

Development: 4808.7 ft., with 4538 ft. of diamond-drill-

ing; estimated ore-reserves amounted to 502,682 tons, with a value of \$5,595,500.80.

Production: 188,835 tons of ore was treated. Bullion containing 99,461.39 oz. of gold and 21,140.3 oz. silver was recovered. The mill operated continuously and satisfactorily. The percentage yield dropped slightly during the latter period of the year, due to the premature precipitating action of graphitic schist in the ore broken from development from the 1250 and 1375-ft. levels. From experiments and large-scale tests it has been decided that this class of ore can most economically be treated by eliminating the graphitic material by flotation before treatment by cyanide. Plans are made and a flotation addition to the mill will shortly be in operation.

DAVIS-DALY COPPER COMPANY

Report for the year ended June 30, 1920.

Property: mines at Butte, Montana.

Operating Official: J. L. Bruce, general manager.

Financial Statement: receipts, \$1,944,600.31; disbursements, \$1,652,421.61; net operating profit, \$292,178.70.

Development: 10,149 ft.; ore-reserves amounted to 257,377 tons.

Production: 122,379 tons of ore was shipped containing 319,334 oz. gold, 902,978.717 oz. silver, and 13,564,064 lb. copper.

YUKON GOLD COMPANY

Special report, dated December 10, 1920.

Properties California and Idaho; Jarbidge, Nevada; Yukon Territory; Federated Malay States.

Operating Officials: O. B. Perry, general manager; C. H. Munro and J. B. Newsom, examining engineers in Malaya.

Financial Statement: Assets (including bullion in transit valued at \$302,559.71), \$7,891,694.52; liabilities, \$5,061,972.73; balance of assets over liabilities, including estimated valuation of properties, \$2,829,721.79.

Development: 2182 acres of dredge ground in Federated Malay States, estimated to yield 75,115,000 lb. tin, after deduction of dredging and smelting losses; 5000 tons of ore assaying 200 oz. silver and 68% lead in Yukon Territory.

Production: At Jarbidge, Nevada, 104,469 tons has been milled to date, yielding bullion valued at \$1,181,900, with net profit of \$555,229. Ore blocked out is estimated to yield a profit of \$500,000.

MOUNT LYEYLL MINING & RAILWAY COMPANY, LTD.

Report for the year ended September 30, 1920.

Property: Mine, mill, and smelter at Mount Lyell, Tasmania.

Operating Officials: Robert C. Sticht, general manager; Basil Sawyer, local superintendent; R. P. Roberts, chief metallurgist; R. M. Murray, mine superintendent; G. F. Jakins, assistant mine superintendent; C. W. Wright mechanical engineer.

Financial Statement: The working account shows a profit of £152,162 7s.3d. The net profit amounts to £76,007 11s.8d., after deducting amounts for prospecting and development, and depreciation of mine plant. The net profit for the previous year amounted to £130,232 18s.1d.

Development: No additions to the ore-reserves of the Mount Lyell mine were made during the year. Additional diamond-drilling at the North Mount Lyell mine, however, has resulted in an addition of 126,873 tons to the ore-reserves. The total ore-reserves on September 30 amounted to 1,802,509 tons at the Mount Lyell mine, with an average assay of 0.50% copper, 1.5 oz. silver, and 0.04 oz. gold; and 1,013,518 tons at the North Mount Lyell mine, with an average assay of 6% copper, 1.33 oz. silver, and 0.005 oz. gold per ton.

Production: The flotation plant treated 34,239 tons of ore, averaging 3.32% copper, producing 9251 tons of concentrate. The smelter treated 169,649 tons of ore and concentrate, producing 4536 tons of copper, 168,109 oz. silver, and 5164 oz. gold, as compared with a production of 5314 tons of copper, 266,864 oz. silver, and 5538 oz. gold, during the previous year.

The company has commenced operation in connection with additional subsidiary industries, including the production of caustic soda and hydrochloric acid by electrolysis.

MOUNT MORGAN GOLD MINING COMPANY, LTD.

Report for the half-year ended November 28, 1920.

Property: Mines, concentrators, and smelters at Mount Morgan, Queensland, Australia.

Operating Officials: A. A. Boyd, general manager; J. Horsburg, assistant general manager.

Financial Statement: Total revenue for half-year amounted to £656,977 7s.6d.; expenditure charged to profit and loss, including development and depreciation, £550,703 9s.0d.; surplus, £106,273 18s.6d.

Dividends: No dividends were paid during the period because of the lock-up of funds represented by the amount of metal in process, the refining of which was delayed by strikes.

Development: The ore-reserves amounted to 3,318,134 tons, containing 2.58% copper and 6.04 dwt. gold, as compared with 3,437,637 tons, containing 2.59% copper and 6.11 dwt. gold, on May 30, 1920.

Production: 106,895 tons of ore treated in the concentration section for the production of 39,436 tons of concentrate. The smelting section treated 98,466 tons of concentrate and ore, and produced 3451 tons of copper and 52,686 oz. gold.

NORTH BROKEN HILL, LTD.

Report for the year ended June 30, 1920.

Property: Mines and mill at Broken Hill, New South Wales, Australia.

Operating Official: G. Weir, general manager.

Financial Statement: Assets show a surplus over liabilities of £469,777 2s.8d.

Dividends: No profit was made during the period, the mine having been closed since May 8, 1919, so far as productive operations are concerned.

Development: On account of labor troubles, no development work has been carried out. The ore-reserves remain at 2,600,000 tons.

The miners' union presented a new 'General Log of Wages and Conditions of Employment', the terms of which are as follows:

Wages: £1 per shift for all men and boys alike, whether working on the surface or underground.

Hours: Six-hour shifts per day on surface and underground, worked only on five days per week.

Night Shift: Abolition of night shift on surface and underground.

Contract System: Abolition of the contract system on surface and underground.

Compensation: Compensation on the basis of full pay for time lost for all complaints and diseases that may be attributed to the unhealthy nature of the work in the industry.

The miners' union refused to consider arbitration, neither would it act on an award made by the State Industrial Court. The company has taken an interest in a British concern promoted for the purpose of manufacturing white lead. Works are under construction at Cabarita, on Sydney Harbor, that will have a capacity of 4000 tons per annum.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

BELT-CONVEYORS ON THE GOLD MINES OF THE WITWATERSRAND

By H. D. Gumbley

In 1886 payable conglomerate ore was discovered on the 'farm' Langlaagte, two or three miles to the west of Johannesburg of today.

The 'reef', extending due east and west for 60 miles from Springs to Randfontein, consists at present of about 135,000 claims, each claim equalling 64,025 sq. ft. or 1.47 acres. Operating these claims are approximately 45 producing mines capitalized at \$750,000,000. These 45 mines operate 7972 stamps, employ approximately 23,000 whites and

crushing-station, and here is found the most severe conditions under which belt-conveyors have to operate. The ore is tipped from the trucks into a bin from which it is conveyed to the crushing-station on belts usually 30 or 36 in. wide, 7 or 8-ply, with $\frac{1}{4}$ or $\frac{3}{8}$ -in. rubber face. These belts travel about 170 ft. per minute.

The size of the rock falling on the conveyor-belt varies from fine gravel to pieces weighing several hundred pounds, and in many instances is sharp and jagged. On the property where this photograph was taken there are four of these belts, each 220 ft. long. No. 1, 2, and 3 drives are equipped with 'Indestructible' conveyor-belts, 30 in. wide, 7-ply, with $\frac{1}{4}$ -in. rubber conveying-face and $\frac{1}{2}$ in. underside.

Sorting-Belt In Gold-Mill on the Witwatersrand

200,000 natives, and mill upward of 2,000,000 tons of ore per month, yielding somewhere in the neighborhood of 700,000 oz. of fine gold which is worth approximately \$18,000,000.

The scope offered by this industry for the sale of mechanical rubber goods is large. Transmission and conveyor belting together forming one of the largest items of mine purchases within the scope of the United States Rubber Co.'s activity. The total value of belting purchased during 1919, according to official statistics, was \$935,000.

I estimate that there are not less than 800 belt-conveyors in constant use on the reef, ranging from belts 18 to 40 in. wide and 100 to 1200 ft. long. These belts handle gold-bearing ore in different stages of its 'refinement' and the conditions under which they have to operate are probably as severe as is met with in any part of the world. The conditions are all the more abnormal, due to the fact that most of the conveyors run under the minimum of supervision. The ratio of cheap colored labor to white skilled being in the neighborhood of about 9 to 1.

The ore is brought from the shaft head to a sorting and

The 'Indestructible' belt on No. 1 drive conveyed 160,000 tons of rock during a life of 15 months.

From the feed-belt the rock passes over grizzly-bars, set at an angle of from 38° to 45°, onto the sorting-belts shown in the accompanying illustration.

'Sorting' means separating and rejecting rock hauled to the surface containing little or no gold. Waste is usually quartzite and is distinguishable from ore, more easily when both have been slightly washed with water to remove any grit that might render the difference less marked. The ore is a conglomerate of quartz pebbles cemented together by a matrix having a dark bluish appearance when freshly mined.

The sorting-belts are usually 30 or 36 in. wide, 7 ply, with $\frac{1}{4}$ or $\frac{3}{8}$ -in. face, and travel at a speed of 30 to 40 ft. per minute. A slow belt-speed is necessary to allow time for picking out the waste rock by hand.

The waste removed is placed on another belt for conveyance to the dump. The life of a sorting-belt varies considerably and depends a great deal on the method of loading. On the particular mine where the photograph was taken, the grizzlies over which the rock passes from the

feed-belts to the sorting-belts are set at an angle of about 40°, and consequently the heavy rock comes down fairly fast and frequently a sharp edge of the rock is driven right through the belt. When this happens the hole which is usually not more than 3 to 4 in. long is repaired with Bristol belt-fasteners.

The writer saw a new 'Indestructible' belt, which had only been on the drive a few days, with no less than three holes through the belt, all caused by excessively heavy rocks coming onto the belt at great velocity.

The ore is delivered by the sorting-belt to the breakers, which are usually of the gyratory or swinging-jaw type. Here the ore is reduced to about 3-in. cube and conveyed to the stamp-mill bin by belt-conveyor.

This belt is 542 ft. long and travels at a speed of 350 ft. per minute at an angle of 18°. Its life is in the neighborhood of 2½ years and it handles in that time roughly one million tons of ore.

The ore is finally delivered from the main belt onto a conveyor-belt called a 'shuttle' belt, running at right angles to the main belt. This belt is on a traveling cradle that runs on rails and moves backward and forward over the stamp-mill bins, discharging into the bins as required.

A SCORE-BOARD AS AN ACCIDENT PREVENTIVE

It has been eight years since the Dodge Manufacturing Co., of Mishawaka, Indiana, first started its accident score-board. During this period thousands of firms all over the United States have asked for the method of operation.

In the first place, when the sign-board was planned, there was no thought of the pioneering that the Dodge Manufacturing Co. was doing in welfare work. The sole idea was to develop some means of cutting down preventable accidents in every department in the plant. W. L. Chandler, supervisor of insurance, decided the best plan to do this work would probably be to make use of a competitive spirit in workmen and foremen. Today, after eight years of operation, the score-board is as much a pride

to the worker-personnel as is a record-breaking pulley or transmission equipment. One represents an achievement in human conservation and the other marks a mile-stone in mechanical progress—both of which are vitally essential to the success of a large organization.

The size of the board erected just inside the main gate of No. 1 plant was 17 by 24 ft., which gave plenty of room for large lettering. The mechanism for scoring points is as simple and fair as possible. The starting point is 1000, both for year and month; each division is penalized according to its accidents; each day's absence bears a percentage charge in proportion to the total number of 'men-days' per month per division.

The departments were divided into 26 divisions, according to the various degrees of natural hazard and variation in numbers of men employed. The degree of hazard is disregarded. The business covers the same general subject throughout the plant; the differentiation being considered as equalized in the choice or selection of men with reference to their ability and fitness for their respective classes of work.

The variation in the sizes and groups of workers was met by establishing a differential charge per man per day for time off, which is computed by reducing each division to men-days for each month, and using a multiplier of 10 to raise the figures to a more workable and understandable basis.

This system of scoring was finally arrived at after considerable experimental work and the present system seems to be fair in every respect and there has been no occasion to change it during the past few years, in spite of the fact that during this time almost every known condition has cropped up.

In the fourth column of this score-board will be noticed the figures which represent deductions for absence in that division.

At the end of each year the employees of the divisions scoring 1000 receive two days extra pay, or such part of that amount as their time and employment bears to a full year. If none score 1000, then the highest ranking division receives the two days pay. General foremen of any division under them earning these premiums.

The original plan was to distribute \$25 in cash each month to all foremen of divisions winning perfect scores, but due to the relative importance and the efforts of the foremen with a widely varying number of men this arrangement was changed so that one-half of each prize is paid on a flat basis and one-half distributed according to the number of men overseen; thus a foreman in charge of 50 men will get a proportionately larger premium than the one in charge of 10 men.

It will be noted that the cash prize is small, and by some it may be even considered as trivial, but it was the intention not to make the men strive only to secure the cash prize as much as to awaken in them a healthy competitive spirit.

Every member of each division is keenly alive to the fact that responsibility for keeping his division with a perfect score rests squarely on him, consequently he gauges his work and actions to conform with all the precepts of safety first. This interest is stimulated and fostered by making up the yearly basis out of the monthly averages. The great thought is then concentrated on the yearly contest, and the discouragement of any unfavorable monthly showing is avoided because any other division may have a penalty sufficient in some months to equalize these unfavorable periodical conditions.

ANNUAL COMPETITION GENERAL

All Departments Scoring 1000 For the Year or the One Having Rank One in Yearly Percentage will Receive Two Days Pay Extra.
Second Highest will Receive One Days Pay Extra.

HEAD FOREMAN WILL PARTICIPATE IN FIRST PRIZE IF WON BY A DIVISION IN HIS DEPARTMENT.

FOREMENS MONTHLY COMPETITION

All Departments Having a Score of 1000 or the Highest Three Scores will Receive Special Prizes as per Monthly Prize List.

PRIZE LIST FOR
MONTH OF October
\$25.00
Equally divided
among the
Foremen having
a perfect score.

The History of the Wilfley is the History of Concentration

It's Still a Question of First Principles

LEAVING out all tricks of freak construction, it is still a fact that table concentration is effected now, as years ago, by means of a light, but strong, rigid deck moving in a perfectly horizontal line connected to a head motion which will impart the greatest amount of travel to the mineral upon the deck with the least amount of external agitation in conjunction with properly adjusted straight line riffles which eliminate the gangue all along the table.

Any attempt to cause material to take any path except that caused by the co-efficiency of the action of the head motion, the wash water and the uniform, properly adjusted riffles is departing from the true principle of table concentration.

To be sure, there has been refinement in Wilfley design and construction, but there has never been deviation from these basic principles.

The 22,000 Wilfleys now in use are the big endorsement for their meritorious work.

T. A. RICKARD, Editor

ATENTION must be directed to a serious typographic error, appearing in our issue of February 12, in connection with the Yukon Gold Company's Malayan enterprise, in which we are made to say that the gravel averages 83 pounds of tinstone per cubic yard. It should be 0.83 pound.

OUR supply of scribbling-paper will be reduced in consequence of the vote of Congress refusing an appropriation for the continuation of the work of the Council of National Defense for the fiscal year 1922. This involves the discontinuance of the Daily Information Digest, which furnished us four or five pages of excellent paper daily, because one side was unspoiled.

PAPER-PULP is now being made in Alaska. We have received a letter written on a sample of the first pulp produced by the mill of the Alaska Pulp & Paper Company, of San Francisco. This enterprise is making use of the water-power developed on the Speel river by Mr. E. P. Kennedy and other engineers identified with the Alaskan mining industry. We hope they may be successful and that in due course the book-paper we use may come from Alaska.

NOW that the suffrage has been given to women, it is not surprising that the proverbial 'better half' is finding her way into new avenues of usefulness. For example, a lady has been elected to the board of directors of an important mining undertaking, the Champion Reef Gold Mining Company of India, which boasts an annual output of \$1,500,000 and workings 5000 feet deep. The lady in question is Mrs. Tennant, the wife of Mr. Harold J. Tennant, who is the brother of the late Lord Glenconner, the third son of Sir Charles Tennant, who, together with the engineering firm of John Taylor & Sons, was largely instrumental in finding the money that started the profitable exploitation of the Kolar gold-field, which includes the Champion Reef, Mysore, Nundydroog, and Ooregum mines, constituting the present gold-mining industry of India. Evidently the wife was preferred to the husband as a director; we are told by the 'Financial Times' that during the War "she herself filled with distinction the post of Government Superintending Inspector of Factories . . . and was one of the first of her sex to be made a Justice of the Peace". Apparently it is a tradition in the history of the Champion

Reef company that the Tennant family must be personally represented on the directorate. This Mrs. Tennant is a cousin of the irrepressible 'Margot', who as Mrs. Asquith, has added to the gaiety of the nations, but it may be inferred confidently that the two ladies are of different mental bias and that the new director of the Champion Reef is the more businesslike of the two, and therefore better fitted to be co-opted as a trustee for the shareholders in an important industrial enterprise.

FROM accounts that have reached us we conclude that the annual meeting of the Institute was a most successful affair. The total attendance was about 800, and the banquet was graced by 689. Not many members came from west of the Mississippi, for the simple reason that the discomfort of travel and the cost of it in these days restrain most people from making the transcontinental journey except when absolutely necessary. The program of entertainment included many attractive features; and as for the smoker! that was a marvel of delightful surprises, thanks to Mr. Mathewson's talent for creating fun. Mr. Hoover stepped down and Mr. Ludlow succeeded him as president. Both made excellent speeches at the banquet, one emphasizing the principle of the 'open shop' and the other the purpose of the Federated Engineering Societies. Reference was made to the San Francisco section and explanations were offered for the deficit in the finances of the Institute. We note, with keen pleasure, that Dr. Henry S. Drinker has been made an honorary member.

IT is a pathetic commentary on modern conditions that the preceptors of the rising generation are generally so poorly paid that they can make little or no effort to collect a fund to offset the physical and mental depreciation of old age, often incurred prematurely by their own unselfish efforts, or to provide adequately for those they leave behind them. We learn with regret that the remuneration received by the late J. J. Beringer, the principal of the Cornish School of Mines, at Camborne, for nearly thirty years, was so little that he was unable to make provision for his widow. His treatise on assaying, like most technical books, was doubtless unremunerative to the author, though of assessable value to the industry. It places Beringer on an international footing with mining engineers. A memorial fund has been opened for

subscription, the interest of which will be given to the widow, the principal being used afterward for scholarships and prizes. Some of our readers will welcome an opportunity of adding to this. We shall be glad to forward any contributions received; or they may be sent direct to Mr. T. Knowles, Mining School, Camborne, England.

OUR friend Mr. F. H. Mason writes on the subject of capitalization, not of companies but of letters; he urges the need for uniformity of style in this and in other literary matters. Every technical periodical has its style, as he says; so we venture to mention one or two of our own rules. In the first place the only President is the Chief Executive of the United States; the heads of companies and institutions are presidents. In the United States, kings are not capitalized, they are liquidated. State and Province are equally honored; so is the Federal power and that of the Dominion. 'Minister of Mines' is a title; so is 'Professor of Mining'; whereas "superintendent of the Bonanza mine" is descriptive; so is "secretary of the Canadian Institute"; 'Provincial' means belonging to the Province, whereas 'provincial' is the antonym of 'metropolitan'. The Government means the administration of the country; a government is of less consequence. A government or a company is a unit, and therefore calls for a singular verb. So does the United States when regarded as a nation. Nothing is more singular than the unnecessary use of the plural.

FROM the latest information available it is evident that claimants under the War Minerals Relief Act have been greatly disappointed. The report sent by the Secretary of the Interior to the Senate shows a total of 1207 claims aggregating \$18,131,493, whereas only \$2,457,259 has been awarded. The total amount involved in the claims on which awards were made was \$7,871,315; the amount involved in the claims still pending is \$3,106,697, and the amount of claims withdrawn is \$646,577. Of the claims disallowed, \$6,506,903 is covered by absence of proof of Government request to claimant to produce War minerals. Of the 1200 claimants, 800 have been denied any relief whatsoever. The result is discreditable to the Administration and a slur on the honor of the United States government. Money was spent lavishly, even recklessly, for munitions and other war materials, and there is no excuse for adopting a meticulously legalistic attitude toward the men who did notable service in providing the minerals from which were produced the metals required for warfare. The denial of \$6,500,000 of claims because the claimants could not furnish proof of direct request from the Government is grossly unfair to the smaller producers, who, of course, obtained their information on the subject by indirect means, as through the columns of the 'Mining and Scientific Press' and other papers, technical and untechnical. The producers of war minerals have not been treated in the spirit with which they went to work, at a time of crisis, in order to assist the national cause; their motives have been subjected to a catechism that was as unjust as it was un-

philosophical, for no act is the product of a single motive. If a man comes to your help when you are asking for it, you do not examine his motives too closely after he has given the assistance for which you ask; you do not tell him that he did it partly to gratify himself, or partly to win the good repute of his neighbors; you thank him and pay him back at the first opportunity. The mental attitude of the Commission reflects no credit on the Government; in trying to be smart, it has succeeded in being petty.

PRIOR to 1898 a first-class brick-mason working under average conditions received 42c. per hour for his work and laid 1500 bricks per day. Since then wages have increased gradually to \$1 per hour, but the daily performance of a mason is measured by the laying of from 400 to 500 bricks. It is true the eight-hour working-day was not in vogue in 1898, but it is also true that most masons today could lay from 1000 to 1200 without excessive exertion. The reason why they do not may be found in the tacit but none the less rigidly observed regulations made by the Brick Masons and Plasterers International Union, whereby a maximum allowable daily stint is established. Since 1898 this maximum has been arbitrarily reduced by successive steps; in 1906 it was 1000; in 1915, 700; in 1919, 600. Brick-masons, of course, are not peculiar in this regard; the same condition prevails in nearly all of the labor-unions, and it is this policy that is driving employers toward the 'open shop'. The payment of wages on a scientific basis recognizes two principles, namely, that the minimum wage should be adjusted to meet the cost of decent living, and that the earnings of different individuals should vary with the competence and industry of the worker, that is, with the quantity and quality of his output. The labor-unions ignore the second principle and advance the theory that the work accomplished by the least skilful and the least energetic shall be the measure of the work done by all. That labor-unions have a place in our economic system, and that they have been instrumental in correcting injustice on the part of employers that otherwise would never have been corrected must be admitted; but the principle of restriction of individual output is unsound, and if maintained it will result in harm to the working-man himself. We believe that an industrial system will ultimately be developed under which the interests of the employer and the employee will agree rather than conflict; when even the least competent can earn an adequate living if he is conscientiously industrious; when each individual will find an incentive to do his best work at all times; and when the employer will find it profitable to pay high wages. Such a program is easy to plan and difficult to accomplish; but therein lies the hope of future industrial prosperity.

ONE Edmond Temple, a gentleman who, had he been alive today, would no doubt have called himself a mining engineer, published, in 1830, a book on travel and mining enterprise in South America. Speaking of the great mines of Potosi, he says: "It has been asserted by

some that the *cerro* of Potosi is of volcanic origin; but this I have heard contradicted in the most positive manner. For myself, I presume not to offer any opinion on the subject; geology is a science which till lately has been strangely neglected, even by those who have received the most liberal education. I may observe, however, that, having visited Vesuvius and Etna, I saw nothing in or about the composition of the mountain of Potosi that resembled or reminded me of either of these two volcanoes. Our chief miner in vain endeavored to discover at or near the mountain anything like pumice-stone, which would have been a convincing proof of volcanic origin, had any such been found." We are not surprised to read, in another part of the book, that the party did all it could in preparation for a tedious time, even to the provision of a quantity "of gingerbread nuts and peppermint drops, to comfort us", as the chronicler quaintly remarks, "on our journey across the continent of South America". The expedition, as one might conjecture, was a failure; and Temple reprints the resignation sent to his board of directors, the concluding portion of which reads as follows: "For my own part, to whatever quarter the storm of life may blow, it will bear me a willing guest; but as it is not to my taste to eat the bread of idleness, more particularly at the expense of others, I have no wish to while away the three years of my contract by concealing from your Board that there is no longer any occasion here for the services of your obedient, humble servant, Edmond Temple." We commend the phraseology to those of gentle nature who, like Temple, are unqualified and unsuited to the actualities of mining work, and who find themselves at variance with their surroundings.

RECOGNITION of a chronic malady is frequently the first step toward its relief. When a man confesses that he is losing his normal vigor, and that he misses some of the resilience of former years, he is likely to see the prudence of paying some attention to his diet; he is impressed with the benefits to be derived from regular hours of sleep; and in other ways he may take care of himself, thereby postponing impending decadence. Something akin to this, we suspect, is the purpose of a bill recently introduced in the Colorado Legislature by representatives from all the mining counties of the State. As Mr. Ezra D. Dickerman of Leadville rather dolefully but frankly remarks, "The mining industry of Colorado needs help"; the State that was once second to none in the value of its mineral production, and in which fifty big mines flourished at one time, has lost its health so far as mining is concerned. Apparently the case has been diagnosed, however, and a prescription prepared, for, to quote Mr. Dickerman again, "If this bill passes the General Assembly it will pave the way to the rehabilitation of the industry in this State". The measure, which is said to have the support of virtually every mining man in Colorado, provides for the appointment by the Governor of a State Board of Mining to consist of nine members all actively engaged in the mining industry, and all of whom are to serve without pay. A tax of one

mill on the value of all metal mines in the State is to supply \$30,000 per year to finance the work of the board, which is to devote itself to investigations concerning prospecting, mining, marketing ores, freight-rates, and smelter charges, the point of view being economic rather than technical. On the face of it, the bill is unique; it seeks neither to create well-paid sinecures for the members of the board nor to augment the State budget by an appropriation from the general funds. The object of having the board appointed by the Governor seems to be to give it standing and to enable it to subpoena witnesses to testify at its investigations. In other respects the result would be the same if the mining companies organized a committee of their own. We refuse to believe that the mineral resources of Colorado are even within sight of exhaustion and we are glad to record any well-considered proposal for giving fresh life to a mining industry that we feel assured is not dying, but in need of adequate stimulus.

Taxation of Mines

This is a problem always fruitful of contention, for the reason that mining property is more difficult than any other to appraise accurately. The result of this difficulty has been the establishment of a variety of methods for determining the tax to be paid by the owner of a mine, together with constant agitation for changes and revisions. A number of western States use the net profit of a mining company as the basis for taxation, by applying the regular levy to a multiple of the profits. The factor used is generally two or three. In Canada, the Provincial Legislature of Ontario has fixed a special rate applicable to the net profits of mines only. A bill is now before the House in session at Toronto proposing to increase the existing rates from 3% to 4% "on the excess of annual profits . . . above \$10,000, and up to \$1,000,000", and from 5% to 7% on the excess over \$1,000,000. For some reason, an exception is made of nickel and nickel-copper mines, the minimum for such properties being 5, instead of 4%, as fixed for producers of gold and silver. This proposed legislation was probably inspired by the immense prosperity experienced by the mines of Cobalt prior to the decline of the silver market in the latter half of 1920. The present bill would doubtless have found more support, because of its sentimental appeal, had the slump not come just when it did. Mr. A. F. Bingham, manager of the Hollinger mine, in a recent address pointed out that the three large mines of the Porcupine district alone paid \$2,500,000 in wages last year, in addition to an approximately equal amount for supplies; he urged that no unreasonable burden be put on an industry of such importance to the welfare of the Province. We can imagine the attitude of the average legislator, who, as he pictures the glittering bars of gold and silver bullion fresh from the mills, concludes that here is an appropriate place to gather the money wherewith to run the government. He probably would not believe it if he were told that, by and large, as much money goes into wages for those who dig in search of ore

as is obtained from the sale of all the metal produced. The prosperity of Northern Ontario depends upon its mines, and any legislative enactment that tends to discourage investment in mining property will retard the development of the industry. The lawmakers should be sure that they do not strangle the goose that lays the eggs of gold—and silver. A revision of the method of taxing the copper-mining companies in the Lake Superior region of Michigan is also under consideration. The present plan is to estimate the value of the property by averaging the market-value of the stock-shares on the 52 Mondays of the year. The regular tax levy is then applied to the valuation thus determined. The proposed method is to appraise the surface improvements at their actual value, and to base further valuation on the quantity and grade of ore mined during the tax year. Just what the details are, we have not learned, but it is said that many of the smaller companies favor the new plan. They are averse to paying taxes for periods when production has been practically nothing, and when the balance-sheet shows an operating loss. And yet the man who owns a farm doesn't think of escaping taxation on the fair value of his land just because he has a light crop or a poor market for his product. However, there are inherent peculiarities about a mining property that make the problem of taxation unique. The prescription of a standard form of financial statement, together with a uniform system of accounting, and the adoption of a tax based on profits is one solution of the problem.

The Education of Engineers

Our 'Discussion' department is enriched this week by a thoughtful and suggestive letter from Mr. Walter S. Weeks, Associate Professor of Mining in the University of California. Professor Weeks writes as a Harvard graduate who has lived in the West, and we find ourselves, naturally, in accord with most of his views. We can imagine how some of his sallies would have tickled Huxley, for it is about fifty years since scientific men succeeded first in convincing an unsympathetic world that culture could come from the study of biology and geology as well as from the learning of Greek and Latin. The echoes of that early conflict of opinions have died away down the aisles of time and the post-Victorian age has accepted the idea that culture resides not only in the knowledge of the classics but in all that concerns humanity and the human effort toward enlightenment. "Education is a continuous process", says Professor Weeks. Yes, indeed. It continues through life, and when it ceases a man is moribund intellectually. John Richard Green, the historian, asked that his epitaph might be, "He died learning". The motto of the school to which the present writer went was, "We learn not for school, but for life". The discontinuity in the education of our mining engineers is its saddest feature. They go to school and college; they come in contact with the best minds, in men and books; they rub shoulders with a liberal culture; and then they go forth to make a career, during which, in many instances, alas, they become too

absorbed to continue the process of education; and by the time their active days are over they are little better than machines ready to be scrapped. The instruction that the average youth undergoes fails in becoming an education; too often it is only a training for earning his daily bread. It ought to be "a power for accomplishment", as the Professor says. To accomplish what? Surely more than making money, for a hod-carrier can do that. After all, what is the purpose of educational effort? To make a man effective in his day and generation, to turn an engineering student into an efficient engineer. But that is not all; we must consider him as a citizen in the community: he ought, by reason of his educational preparation, to be a better husband and a better father, a better citizen; he ought to be happier for his mental training and he ought to contribute in larger measure to the happiness of his fellow-men. We agree that the so-called broad education should not involve the sacrifice of precise knowledge on the matters that more particularly concern the engineer as a technician, for a man is not likely to be happy or to make others happy if he fail to do his own work well. Indeed, the discussion can be brought down to the question of the amount of general culture that can be absorbed without trespassing upon the time needed to learn how to obtain one's bread and butter, plus a reasonable addition of condiments. "Art is long and time is fleeting", and the budding engineer cannot acquire all the learning or gain all the accomplishments that a fairy godmother might wish for him. The European goes to one extreme, the American to the other. In the old world they strive for culture at the expense of practical training; in the new world, our young men look to the main chance and forego those things that are more excellent. It is a tremendous problem. We agree with Professor Weeks that it is absurd to suppose that general mental culture can be obtained in a mining college, or even in a university; the seeds of it must be planted earlier, in the home and in the preparatory school; the university will encourage them to take root and grow to fruition. A liberal education cannot be planted on sterile soil. Some questions are answered best by stating them in terms the truth of which is incontrovertible. What is a "liberal education"? Let Huxley answer once and for all:

"That man, I think, has had a liberal education who has been so trained in youth that his body is the ready servant of his will, and does with ease and pleasure all the work that, as a mechanism, it is capable of; whose intellect is a clear cold-logic engine, with all its parts of equal strength, and in smooth working order; ready, like a steam-engine, to be turned to any kind of work, to spin the gossamers as well as to forge the anchors of the mind; whose mind is stored with a knowledge of the great and fundamental truths of Nature and of the laws of her operations; one who, no stunted ascetic, is full of life and fire, but whose passions are trained to come to heel by a vigorous will, the servant of a tender conscience; who has learned to love all beauty, whether of Nature or of art, to hate all vileness, and to respect others as himself."

A Nice Point

A question of professional morality has been raised in connection with the employment by the Dupont company, at high salaries, of two expert dye chemists, recently arrived from Germany. These gentlemen were released from Ellis Island on January 5, after an investigation had been made by the immigration authorities, following the receipt of a protest from Germany against their detention. It is reported that warrants were issued for their apprehension in the fatherland, and these they succeeded in evading. This official interference is interpreted as a move to prevent the development of a dye industry in this country that would interfere with the German export trade. Germany is chagrined at the disloyalty of her scientists. The Dupont company, according to the press, has issued a statement excusing its action on the grounds that the Germans were needed "to interpret and help put into practical operation the processes and formulae covered by the patents seized when this country went to war with Germany. In many cases the records filed with the Patent Office are incomplete, giving misleading information, and are otherwise so craftily devised that only a German chemist can put them into practical use. The American chemist has already solved so many of the problems involved in the manufacture of dyes that about all that is needed from Germany is the worker experienced in the manufacturing end of the business." This explanation is somewhat inconsistent with the fact that Dr. Otto Runger and Dr. Joseph Flachländer are evidently of the expert class. The salary to be paid each for their services here is rumored to be \$25,000 per annum, and may be even more, for no denial of the more modest estimate has been forthcoming from the American company. Our contemporary, the 'Journal of Industrial and Engineering Chemistry', takes exception to the action of the Dupont company and considers it unfortunate, viewed from any angle. It points out that an economic battle for the possession of the American market is in progress between the American and the German dye industry. Although in war-time, information is obtained, we are reminded, as far as possible from captured opponents, it is not usual to place renegades in positions of high command. Our contemporary regrets the policy of the Dupont organization, hitherto considered 100% patriotic, and views askance, as a matter of national concern, the demoralization in the ranks of American technicians in consequence of the lowered morale of the Dupont research staff. Whatever the ability of the two chemists, it concludes, however intimate their knowledge of special lines may be, it were better to send them home and let the American industry proceed to its full development in an American way and by the force of American brains. We find ourselves in full accord with the vigor of the closing opinion, for we would like to think that American effort can reach the top of the tree without help from German technologists; and we consider that if the Dupont company cannot compete with Germany, with the aid of unlimited

capital and American resourcefulness, there is something seriously wrong with its organization. We read in a San Francisco paper, which we are quite unable to designate as an esteemed contemporary, apropos of the baseless charge against Mr. Bernard M. Baruch: "Personal honesty is a luxury, and Mr. Baruch is rich enough to afford it." This, it seems to us, is a crude expression of the same sentiment as that prompting the engagement of the German renegades by the Dupont company.

The Licensing of Engineers

In our last issue we published a summary of a law recently introduced in the Montana legislature providing for the creation of a State Board of Engineering Examiners for the purpose of licensing professional engineers. Accompanying the summary were affirmative arguments prepared by the Montana Assembly of the American Association of Engineers, who sponsored the bill, and a number of objections advanced by a committee of the Montana Section of our own Institute, included in which were a number of men who enjoy more than local prominence in the profession. Some fifteen States have made statutory provision for the compulsory registration and licensing of architects, and a less number have laws imposing similar requirements on engineers and land-surveyors. The American Association of Engineers, through its local assemblies, is advocating the passage of licensing laws in every State, the ultimate aim being to have one comprehensive statute applicable to members of all the engineering professions as well as to architects. We understand that Engineering Council, before it was dissolved, took cognizance of the movement in favor of licensing, by urging that engineers exert their influence to see that if laws were to be passed they might be good ones. The attitude of the Council was that laws would be enacted eventually and that it therefore behooved members of the profession to frame the measures themselves, rather than to leave the matter to those not qualified for the task. The question is asserting itself undeniably; it is one that commands the attention of every engineer. The importance of a favorable attitude on the part of the public is recognized, and in order to cultivate sympathetic relations, an appeal is made on the basis of public service; it is declared that the object of legislation is to "safeguard life, health, and property" by preventing the incompetent, ignorant, and unfit from practising. Analogy is drawn with the State regulations dealing with the practice of medicine, dentistry, law, and pharmacy. However, even at the risk of being thought cynical, we venture to say that the public welfare is a secondary, though important, consideration, and that the primary object of such legislation is to benefit engineers, both as a class and as individuals. Much the same motives are paramount in the minds of physicians when they oppose chiropractors. Nor is this unreasonable. Undoubtedly the obligatory compliance with certain standards of education and experience adds to the prestige of the doctor and the

lawyer; it gives them influence in the community and it enables them to sell their services to better advantage. Frankly, we believe that this is the purpose of the engineers who are favoring licensing laws; this they tacitly admit when they propose that the expense of administering the law shall be met by the engineers themselves; and in 'Professional Engineer', the monthly organ of the American Association, little attempt is made to conceal the fact. The relation between the medical profession and the public is different from that between engineers and the public, but there is certainly as great a difference in the relations of doctors and of attorneys, each with the public. On the whole, it is hard to see why engineers should not look confidently for a higher standing as a result of the general establishment of a licensing law.

Some divergence of opinion is evident as to just what policy is the best to follow in framing a satisfactory law. One proposal is to make it a misdemeanor, punishable by fine or imprisonment, to practise professional engineering without a license, 'practising' being so defined as to include only those in responsible authority. The effect of such a law would be to compel individuals or corporations to employ none but registered engineers in executive and authoritative capacities. Others take the view that it is unwise, even if it be possible, to interfere in any way whatever with the freedom of the private employer, as distinguished from the public officials, in the selection of those who are to do engineering work. They contend rather that legislation should be directed toward protecting the title 'professional engineer' by making it unlawful for a person not duly licensed to use the title or pose as an engineer. It would remain, then, to make the word 'engineer' synonymous with efficiency and competency in the performance of work requiring special knowledge and skill; it would be necessary for engineers themselves to aim constantly at higher standards of conduct in their technical and professional relations with the public, to the end that the right to use the title would connote ability and training. The committee of mining engineers mentioned criticizes the proposed bill for a number of reasons. First, it is declared to be poorly drafted; certain sections seem to be inconsistent with respect to each other; and the definition of 'engineering' is open to objection. However, these are not vital defects, and we believe that the proponents of the bill would accept gladly amendments designed to correct them. The second argument is that the law, if passed, will not exclude either the incompetent or unscrupulous practitioner. The report says, "Lack of employment does now, and will continue in the future to, curb sufficiently the activities of the incompetent engineer. The proposed law presupposes inability on the part of the employer to correctly judge the competency of his employee". Although there may be reason in this argument, it is nevertheless easy to see that much time and money now wasted in unearthing incompetency might be saved by a well-organized State board of examiners. One point that the mining engineers appear to have overlooked is the fact that State, county, and

municipal governments, which under any legislation should be compelled to employ licensed practitioners, do a great deal of engineering work. Occupants of lucrative and responsible positions are too frequently selected for their ability to construct political 'fences' rather than for any other engineering attainments. The financial loss to the public is not measured by the salary of the particular official, but by waste and inefficiency in the work under his direction. It is on this account that the problem becomes the concern of every tax-payer; the incidence, being through his pocketbook, is felt keenly. As for the unscrupulous engineer, the committee says: "The real injury to the engineering profession comes from men who are competent enough, so far as examinations show. Their sins are not mistakes but misrepresentations." Obviously it is difficult to exclude those who are inclined toward dishonesty; and, although provision is made for the revocation of licenses on the ground of fraudulent practice, such action on the part of the board is necessarily open to review by the courts, where legal proof is hard to establish. However, the existence of machinery for ventilating such matters in public would doubtless be a deterrent to some who otherwise might be tempted to deceitful acts; and, moreover, publicity would make the repetition of unscrupulous conduct by the same individual less likely. One outstanding mistake in the law as drawn is the exclusion of non-citizen engineers from practising in Montana. Apropos of this point, it is fair to remark that there are strong advocates for the entire disregard of the question of citizenship in issuing permanent licenses, and, furthermore, for some provision regulating the issuance of temporary certificates to foreign engineers who are to be retained for special work in this country. American engineers are permitted to practise their profession in every country in the world, with no restrictions other than that they behave themselves. There ought to be no discrimination against non-citizens; and we believe that this policy represents the best thought among those who favor licensing. In our opinion the most important fault of the Montana law is that it presumes to make obligatory the employment of none but registered engineers by private individuals and corporations. The time may come when such a law is desirable; indeed, with respect to certain prescribed kinds of work, compulsory employment of licensed engineers is provided in a number of States today. A successful law must be supported by the conviction and the goodwill of a liberal majority of the people, and in accomplishing any reform it is first necessary to overcome the inertia of indifference. The American Association of Engineers is a growing body of young men; it has enthusiastic leaders who are devoting a great deal of energy to the advancement of the welfare of engineers; among other things, to the passage of licensing bills. If a wise course is steered, and due regard is paid to the advice of the older members of the profession, the Association will doubtless accomplish what it has undertaken; and, as we have said, the prestige, the influence, and the standing of engineers ought thereby to be raised.

DISCUSSION

The Education of the Mining Engineer

The Editor:

Sir—Apropos of the discussion on this subject appearing in recent issues of your paper: there are fashions in education as there are in clothes. What then should be the fashion adopted for the training of the mining engineer? At present the latest word seems to demand a dress of liberal culture. We hear the cry to lay aside much of the drab tweeds of technical training and to substitute therefor the more comely garments of the humanities. In other words (if I may escape from this dress-maker's metaphor) there is agitation toward the widening of the curricula so that they may include such subjects as literature, history, and economics.

Most of us would subscribe quickly to the proposition that an engineer should be a man of culture. But what, pray, is culture?

When the world was young its people soon found it necessary to develop means of communication, so language and literature were born. When things started to happen, history began. Hence it is quite natural that a knowledge of these subjects was considered the criterion of culture, for the simple reason that they constituted the greater part of human knowledge.

As time went on, however, intellectual curiosity reached out its octopus-like tentacles to grasp a bit of fact here and a scrap of observation there and to carry them to its maw, where they were digested and made a part of the ever-increasing body of learning.

Yet the old badge of culture still survives. The man who talks of books and events holds his hearers spell-bound. What a prodigy of wisdom! How different he is from yon silent individual among the listeners. Why has that person not improved his opportunities? He has, do you say, a deep knowledge of astronomy and geology and zoology? Then why does he not make the fine figure of the talker? Because others do not speak his language. A rudimentary knowledge of English suffices to make the speaker's points intelligible, but to understand our silent friend we must have studied a bit ourselves. He may, of course, descend to scientific baby-talk, but even that might tax the brains of the hearers and they would soon turn away.

So here we have two men versed in different subjects. Can the one who has never heard of the equation of time, or a plutonic rock, or natural selection, lay better claim to the medal of culture than he who knows naught of the 'Sentimental Journey' or the Hegira of Mohammed? Unfortunately, yes, for the guild of culturists is like

most exclusive societies: the charter members make the eligibility rules. They had a good many years start on the scientific fellows and became well entrenched amid their ancient lore before the upstarts applied for membership.

Are there not other possible attributes of culture? Why, of course, an appreciation of art and music and drama. What of manners? Is the learned doctor with the refinement of an ourang-outang a model of culture? Hardly. Is not then our ideal of a cultured gentlemen a sort of composite fellow: an Addison, a Newton, a Ruskin, and a Chesterfield all rolled into one?

Few of us can attain to this ideal in a lifetime of striving. How futile it is then to believe that four years of study in a university will enable us to gain the many-sided development that is demanded for true culture, and how infinitely more absurd it is to conceive that four or five courses squeezed into a mining program will accomplish this result. Education must be a continuous process, beginning with the dawn of consciousness and lasting till we cease to register.

Some twenty years ago I entered Harvard and was presented with a catalogue from which I was to select seventeen and a half courses. The completion of these courses would entitle me to a Bachelor of Arts degree with all the privileges and insignia pertaining thereto. The opportunity being at hand, I started to absorb such funds of information as had accumulated up to that time. Four years later I looked back along the way I had come. The gates of many pleasant gardens had opened to me but there had been time scarcely to glimpse their inviting paths. A few nuts of culture shaken down by perspiring professors had, to be sure, landed near me, but the great outstanding truth that had been forced upon me was the fact that the bounds of human knowledge transcend the vision of any one individual, and likewise, as a necessary corollary, that the fellow next to me is not necessarily a barbarian because he is not interested in the subjects in which I am absorbed.

In the light (or the shadow) of what has gone before, let us consider the work of the mining student. In his four-year program he completes about twenty full-year courses. The work of a mining engineer demands the study of mathematics, physics, chemistry, and a goodly number of subjects commonly included in the training of civil, mechanical, and electrical engineers. The substance of the courses in the last three branches, if analyzed, will be found to be an expansion of the course in general physics. In the program are also a few mining subjects. These usually include mine accounting and

mine economics. After all, economics is economics whether we speak in terms of copper and lead and miners, or of corn and wheat and factory workers. A lot of un-studied talk is made against "pastical courses". I presume that the furor is really directed against courses in shoveling and single-jacking. No self-respecting school, however, can find time for such.

In mining we study subjects, not courses. It does not suffice the mining student to select an elementary course in geology and call it a day. The miner must study determinative mineralogy, crystallography, petrology, general geology, economic geology, and he must spend much time in the field. Moreover, even to begin this subject he must have a substantial groundwork of physics and chemistry. He must build a firm foundation of geological knowledge and methods upon which he may rear a more stately edifice from his later experience. And so with his other subjects, they are built up, course by course, until they become a power for accomplishment. In this process of foundation building, unless the teachers are much remiss the student cannot but gain the power of clear thinking.

It is footless to say that the boy needs no specific knowledge—just a broad (?) education. These students at graduation do not become captains of industry, they become the technologists of the mining business. Many of them by nature are fitted to remain technologists, and fortunately this is so, for if they all became general managers it would be embarrassing. One superintendent told me that he never hired students from a certain mining school because they had so many electives that he could never be sure that they would understand the subjects for which he wanted the men. Mining engineering and medicine are alike in that both require definite knowledge in certain fundamentals. Suppose a young mine surgeon was called to treat a man with a broken arm and the doctor should say that he had not elected the course in bone-setting and so could not help the man. Perhaps he could follow the example of the old physician who used to throw all patients into fits because he was 'hell on' fits.

Now it must be admitted that the courses in the mining curriculum embrace material that is ranked as basic in any educational scheme. If we agree that our specification of a cultured man calls for a knowledge of science as well as of letters, then if our mining students were studying solely to acquire culture they would be doing as much as is possible toward that end in the allotted time. Shall we be less thorough in order that we may bow to the popular delusion that the enrolment in four or five random courses constitutes the acquisition of culture? Rather let us find other times for other subjects. What of the student's years from six to eighteen? Is his training during this impressionable period filled with chaff? Is he guided by underpaid drudges? Check up those years and see to it that they are fruitful. The subject of English composition, for example, should have reached such a stage during this time that the student in college does not need additional instruction, but practice, in the art of writing. He should be capable of criticizing

his own work. We are burdened with men who during their school years have failed to meet their intellectual obligations and now expect the university to pull them out of bankruptcy.

Then we must not forget that we can leave a few things for the after-years. The reading of philosophy or the extended study of history might well engage our leisure moments.

Some claim that the engineering course should, like many law courses, be superimposed upon a more heterogeneous course. This might be arranged if all the mining schools made the same requirement. It was tried at Harvard and a vigorous school died from lack of students. Even assuming that the plan were feasible, it would have its difficulties. When the college graduate enters the law school he starts at once on his chosen subject and is carried along by its novelty and interest. In the case of a graduate entering a mining school, we have the condition of rather mature individuals with firm convictions as to their needs, forced into two years of elementary grind during which time they scarcely hear the word 'mining'. From my experience with this type of student, I would say that they will prove to be refractory ore. I would rather see the order of study reversed.

But, you may say, let them take the elementary subjects in the College of Letters. This is possible if they know what they are going to do and will follow advice. If they do this, their technical course will be shortened automatically. This amounts to the same as lengthening the four-year course to possibly six years.

In any lengthened course those with a love for learning will profit while others will take the uplift courses like so much castor-oil. There is a common misconception that students, if given the time, will browse in the library. Moose browse, students go to dances and play games. An extended course requires a lot of money. Many of the students, in the Western schools especially, are partly self-supporting. Their families, by great sacrifice, help them through four years. Any additional burden would mean that the boy would not go to college at all. Finally, in this connection, the young engineer must often spend the years of his apprenticeship in places where life is hard, so the sooner he gets out the better.

To those who are financially able and would really profit by additional years I would say, stay longer. To such men the mining school that is a part of a university offers unlimited opportunity. Speaking of this type of school brings to mind a point that should not be overlooked. A mining student in such a school will absorb much of other subjects from the inspiring activities of the place and from contact with his fellows in other departments. Gordon McKay realized this when he left a fortune to Harvard that a scientific school might be founded in the shadow of a great university.

Regardless of educational systems, some will be cultured and some will not. If we make a slight change in some lines in 'Fanny's First Play' perhaps they will express the real truth of the matter: "Unless people have"

the desire for culture "within themselves, all the earth, all the floods, and all the prisons in the world can't make them really" cultured.

WALTER S. WEEKS.

University of California, February 14.

A Louvred Bin

The Editor:

Sir—The design of louvred bin given in your issue of January 15 is interesting, and suggests a valuable improvement on the design of bin indicated. Everyone who has handled ore, and especially run-of-mine, in such

bins, knows only too well the difficulty of maintaining anything in the way of a regular feed onto a belt-conveyor; in fact, even with the improvement shown, it is well-nigh impossible with the belt in the position indicated. In the accompanying sketch I give what, in practical experience, was found to be a big improvement on an almost similar bin to that you illustrate. The fundamental idea is to create what in hydraulics is known as a 'break-pressure' station in the stream of ore. It is true that a laborer has to keep the ore 'moving' above the feed-chute, but with the wide and continuous exit from the main bin this is an easy matter.

Mexico, D. F., January 24.

W. M. HUTTON.

Institute Affairs

The Editor:

Sir—It appears to be a matter of great importance by what means the A. I. M. E. may be extricated from its present state, toward which it has been drifting for some time. It is to be admitted that some mighty bright men have served as its presidents in the past several years, but we are also aware that such title is largely honorary, and that as such they have little to do with the policies outlined by the Board of Directors. Hence constructive criticism should be acceptable, more especially at the present time.

It appears to me, separated afar from its actual workings, except through correspondence, that, in the 38 years that I have been affiliated with this very able body of engineers, we have become unwieldy through the policy inaugurated that has produced our enormous

growth, which was intended to lessen costs that have nevertheless increased, either through natural causes or by reason of our being compelled to cater to the many different classes of engineers whom we have admitted to membership.

For some time it has been evident that unless these policies were changed, the A. I. M. E., would disintegrate. However, the preservation of the original ideals of the founders should be kept in view, and this can be done by utilizing the best talents of this body in solving the very grave problems now before it. In detailing some of our inefficiencies, I may say that the articles composing a great proportion of our volumes, and in some cases entire volumes, are upon subjects uninteresting to the rank and file. As compared with the earlier years of the Institute, editing appears to have been well-nigh discarded, in eliminating entire articles and in cutting down the remainder. The 'Magazine', one in appearance only, can be safely dropped in almost its entirety.

In addition to an authorized increase in annual dues, the Secretary has called upon the membership for a donation of \$10 each. Gifts can be only palliative and soon would require duplication. If we survive we must be placed upon the sound business basis from which we have departed, and to that end committees should be appointed, consisting of our most able men of each of the different classes of engineers and metallurgists, to go into conference and submit plans for the complete re-organization of the A. I. M. E., yielding to kindred organizations that portion of our membership that is entitled to such, in order that they may be treated more justly, and in justice to ourselves.

WALTER W. WISHON.

Searchlight, Nevada, February 21.

The Editor:

Sir—Recent editorials and correspondence in your paper in criticism of the management of the American Institute of Mining and Metallurgical Engineers suggest the tendency, inherent in all great organizations, toward the dissipation of energy and the distraction of attention to the detriment of the purposes for which they were founded. It is the penalty exacted by size, and a professional society can no more escape it than an overgrown university, state, or religion. Therefore I heartily second the proposal of your correspondent, W. O. Borchardt, in your issue of February 12, that the members "fill out a questionnaire, the results of which would serve as a guide to the authorities of the Institute in the re-consideration of the functions and activities of the Institute".

I must dissent, however, from your editorial comment of the same date that the Mining and Metallurgical Society of America "in its effort to be select has succeeded in being exclusive". The purposes of the Institute and those of the Society are quite distinct, the one seeking to benefit its individual members through the publication of technical papers, while the other ignores technology and concerns itself only with the profession and the industry

as a whole. I feel safe in asserting that the Society, so far from cherishing any ambition to be exclusive, welcomes to its membership every engineer qualified according to a standard no more exacting than that of any bar association or medical society. Since, however, in lieu of material advantages, it has to offer its members only the opportunity for unrequited and even unrecognized service, it cannot make a wide appeal and its ranks must remain thin for other reasons than choice.

Though addressed primarily to your personal attention you are free to use this in any way you may choose.

New York, February 16.

H. H. KNOX.

The Editor:

Sir—The discussion of Institute affairs, both editorially and by members who have taken the trouble to write letters on this subject, will doubtless result in some good; but I wish at this time to urge upon all members of the local section that they attend our next meeting on March 8, as it is quite likely we shall have a further communication from the office of the Secretary by that time, and at any rate, further discussion will result in healthy progress toward the desired end, which is a correction of the ever-mounting cost of membership in the A. I. M. E.

I agree with Mr. Borchardt that "abuses taken in time could have been corrected without disturbance", and those having at heart the prosperity and true success of the Institute should exert themselves, speak their minds, and aid, by concerted action, the laudable desire that has been voiced by our local section in asking the appointment of a committee to investigate the whole question of publication costs. So, therefore, let me urge upon every member of the local section that he set aside Tuesday evening, March 8, for attendance at the meeting of the American Institute of Mining and Metallurgical Engineers.

Teaching Engineering Students to Write

The Editor:

Sir—In Homer A. Watt's interesting address, read before the National Convention of Business Paper Editors, which was published in your issue of February 5, he concluded by suggesting what editors might do toward encouraging engineers to express themselves clearly. As Mr. Watt says, editors already have done much in this direction, and, I might fairly add, probably no one more than yourself. Not only have you contributed two excellent text-books on the subject, 'A Guide to Technical Writing' and 'Technical Writing', but by editorials, by the publication of articles, and by the encouragement of discussion on the topic, you have kept the matter before the mining profession since you dropped the pick to take up the pen, some 18 years ago. What you and others have accomplished may be seen readily by comparing the leading technical magazines of today with those of twenty years ago. There is, however, one direction in

which I believe editors still might do much toward the advancement of technical writing, and that is by conferring and adopting a uniform style with regard to capitalization and the numbers of verbs governed by collective nouns.

As things stand today, nearly every technical paper has a style of its own. Particularly is this noticeable in the matter of capitalization and in the numbers of the verbs governed by and in the pronouns standing for collective nouns; and often there seems to be no consistency in this respect. One finds, for example, in the same magazine reference to John Jones, Minister of Mines, and William Smith, superintendent of the Bonanza mine; a delightful Province and a prolific country: the President and the king. British papers often have a way, like the muse of old, of emphasizing common nouns by capitalization, thus we find "Ontario could have three great Provincial Universities", "Both these Universities have a good Arts course", and "A chart has been prepared to accompany this Report". Editors particularly seem to be at variance as to whether state, province, dominion, and federal should be capitalized or not. Since we do not, as a rule, capitalize earth, world, and continent, there seems to be no good reason why we should capitalize the lesser divisions of them. I understand, of course, that one usually writes the State of California or the Province of British Columbia, in the same way that one writes Doctor Jones or Professor Smith, while one does not write John Jones is a clever Doctor, but some editors do not capitalize state and province even under these conditions. In many magazines and daily papers one finds such words as government and company indifferently followed by singular or plural verbs, and it is not uncommon to find both singular and plural verbs governed—or rather ungoverned—by the same subject. Such forms of writing lend variety, of course, but they are puzzling alike to the reader and to the contributor. The reader, especially if he also is a writer, is apt to fall into the Henry James habit, and find himself reconstructing the sentence, instead of attending to the text. In other words, it discourages concentration.

For the free lance, who may be writing for fifty or a hundred different magazines, it is quite hopeless to attempt to fall in line with the style of any one magazine; the only thing for him to do is to adopt a course of his own, and this often causes trouble and unnecessary labor in the editorial offices. It may be argued, of course, that when a man is writing for a particular magazine, in common courtesy to the editor he should try to adopt the style of that magazine, but, unless the work is being written to order, it often happens that an article written with a particular paper in view does not, for any one of a dozen reasons, meet the editorial requirements; consequently the article is returned, and ultimately may find a niche in a paper that has a totally different style to that for which it originally was written. Bearing this in mind, the value of a uniform style will be evident.

ELY, NEVADA, FIFTEEN YEARS AGO. ROBINSON CANYON IN THE BACKGROUND

Nevada Consolidated Copper Company—I

History of the Enterprise

By Arthur B. Parsons

Mines are like men in that their early history becomes a matter of general interest only when fame and fortune have been attained. Great success in mature years lends the glamor of romance to a story that otherwise would be considered commonplace; it makes worth recording events that in themselves are not exceptional. The Nevada Consolidated had distributed \$45,269,023.85 to its shareholders up to January 1, 1920, and on that date still had a surplus of \$8,160,533.02 as a result of its operations over a period of 10 years. This alone should place the enterprise safely within the category of great mines, and thereby justify a glance at its early history.

The old residents of Ely, which since 1887 has been the county seat of White Pine county, Nevada, and which is about midway between Ruth, where the mines are situated, and McGill, the site of the mill and smelter, keep their memories fresh by recalling the following sequence of dates: '49, the gold rush to California; '59, the discovery of the Comstock; and '69, the great Hamilton-White Pine rush. Hamilton enjoys some conceit in the association, whereas Austin, Eureka, and Pioche, with no less claim to fame, are excluded from the trinity because their birth-dates lack the magic digit 9. The mines of Hamil-

ton, 25 miles west of the present Ruth, were among the most remarkable producers of high-grade silver ore of which we have record. Rich deposits of chloride and bromide ores were found at the grass-roots, and how many millions of ounces of silver bullion were shipped from Hamilton will never be known. The story is told that a mining man telegraphed to Government officials at Washington who were debating the advisability of resuming specie payment during the period of reconstruction after the Civil War, telling them to go ahead, because there was "enough silver in Treasure hill alone to pay the entire national debt". Tradition has it that this same telegram was used by the advocates of the gold standard in their successful campaign for the demonetization of silver, the event that put so many silver mines in Nevada out of business. Doubtless the importance of the part played by this innocent telegram is exaggerated; but the tale emphasizes the richness and extent of the ore deposits. It is said that a single chunk of almost pure hornsiver, or cerargyrite, weighing 2800 lb. and worth more than \$40,000, was taken from the Eberhardt mine.
